- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including ritonavir. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.
- Observe patient for redistribution of body fat, including breast enlargement, central obesity, development of buffalo hump, facial wasting, and peripheral wasting, which may produce a cushingoid-type appearance.
- Monitor patients with hemophilia for increased bleeding, because spontaneous skin hemarthrosis and hematomas have occurred in these patients while taking ritonavir. Provide supportive care, as prescribed.

## **PATIENT TEACHING**

- Instruct patient to swallow tablets whole and not to break, chew, or crush them.

- Tell patient prescribed the oral solution that the taste may be improved by mixing with Advera, chocolate milk, or Ensure within 1 hour of dosing.
- Instruct parents to mix oral powder with soft food such as applesauce or vanilla pudding or mix with liquid such as chocolate milk or water. The bitter aftertaste may be lessened if given with food.
- Warn patient switching from soft gel capsule form to tablets that he may experience an increase in gastrointestinal side effects such as abdominal pain, diarrhea, nausea, and vomiting, but that these adverse events may decrease over time.
- Instruct mothers not to breastfeed while receiving ritonavir therapy.
- Warn patient that fat distribution may occur with ritonavir therapy, altering appearance.
- Alert female patients using oral contraceptives or patch contraceptives containing ethinyl estradiol that alternative methods of contraception should be used.
- Tell women of childbearing age to report a known or suspected pregnancy.
- Inform patients with hemophilia of increased risk of bleeding and the need to seek immediate medical attention if bleeding occurs.

**WARNING** Instruct patient to report any signs of skin abnormalities, especially a skin rash, immediately to the prescriber.

- Warn patient to alert all prescribers of ritonavir therapy, because serious drug interactions can occur.

# rivaroxaban

## Xarelto

### Class and Category

*Pharmacologic class: Factor Xa inhibitor*  
*Therapeutic class: Anticoagulant*

## Indications and Dosages

- *To reduce the risk of stroke and systemic embolism in patients with nonvalvular atrial fibrillation*

### TABLETS

**Adults with creatinine clearance greater than 50 ml/min.** 20 mg once daily with evening meal.

**Adults with creatinine clearance between 15 and 50 ml/min.** 15 mg once daily with evening meal.

- *To prevent deep vein thrombosis, which may lead to pulmonary embolism following knee or hip replacement surgery*

### TABLETS

**Adults with creatinine clearance of 15 ml/min or greater.** 10 mg once daily begun 6 to 10 hr after surgery once hemostasis has been established and given for 12 days after knee replacement surgery and given 35 days after hip replacement surgery.

- *To treat deep vein thrombosis or pulmonary embolism*

### TABLETS

**Adults with creatinine clearance of 15 ml/min or greater.** 15 mg twice daily with food for 21 days, followed by 20 mg once daily with food.

- *To reduce risk of recurrence of deep vein thrombosis or pulmonary embolism*

## TABLETS

**Adults with a creatinine clearance of 15 ml/min or greater.** 10 mg once daily with food for at least 6 months.

- *To prevent venous thromboembolism in acutely ill medical patients at risk for thromboembolic complications not at high risk of bleeding*

## TABLETS

**Adults with a creatinine clearance of 15 mg/ml or greater.** 10 mg once daily, in hospital and after hospital discharge, for a total of 31 to 39 days.

- *To reduce risk of major cardiovascular events in patients with chronic coronary artery disease or peripheral artery disease*

## TABLETS

**Adults.** 2.5 mg twice daily with 75 or 100 mg aspirin once daily.

## Mechanism of Action

Selectively blocks the active site of factor Xa, which plays a central role in the cascade of blood coagulation. Without the action of factor Xa, blood clotting is impaired.

## Contraindications

Active pathological bleeding, hypersensitivity to rivaroxaban or its components

## Interactions

## DRUGS

*anticoagulants, aspirin, clopidogrel, dual antiplatelet therapy, fibrinolytic therapy, heparin, NSAIDs, other antithrombotic agents or platelet aggregation inhibitors, selective serotonin reuptake inhibitors, serotonin-norepinephrine reuptake inhibitors, warfarin: Possibly increased bleeding risk*  
*combined strong CYP3A and P-glycoprotein (P-gp) inducers such as carbamazepine, phenytoin, rifampin, St. John's wort: Decreased effectiveness of rivaroxaban*  
*combined CYP3A4 and P-gp inhibitors such as conivaptan, diltiazem, dronedarone, erythromycin, fluconazole, indinavir/ritonavir, itraconazole, ketoconazole, lopinavir/ritonavir, ritonavir, verapamil: Increased rivaroxaban exposure resulting in increased bleeding risk*

## Adverse Reactions

**CNS:** Anxiety, **cerebral hemorrhage**, depression, dizziness, epidural hematoma, fatigue, hemiparesis, insomnia, **subdural hematoma**, syncope

**GI:** Abdominal pain, cholestasis, **cytolytic hepatitis**, **GI bleeding**, jaundice, **retroperitoneal hemorrhage**

**HEME:** **Agranulocytosis**, **excessive bleeding**, **hemorrhage**, **thrombocytopenia**

**MS:** Back or extremity pain, muscle spasm

**RESP:** **Pulmonary hemorrhage** with or without bronchiectasis

**SKIN:** Pruritus, **Stevens-Johnson syndrome**

**Other:** **Anaphylactic shock**, **anaphylaxis**, **angioedema**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**

# Childbearing Considerations

## PREGNANCY

- Drug has the potential to cause fetal harm as a result of bleeding at any site in the fetus and/or neonate from drug use during pregnancy.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Drug may increase the risk of bleeding for both mother and fetus/neonate during labor and delivery.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## REPRODUCTION

- Women of childbearing age should discuss pregnancy planning with prescriber.

# Nursing Considerations

- Know that rivaroxaban should not be given to patients with moderate or severe hepatic impairment, to patients with any hepatic disease associated with coagulopathy, and to patients with a creatinine clearance that is less than 15 ml/min. Monitor patient's hepatic and renal function, as ordered, throughout rivaroxaban therapy.
- Know that rivaroxaban should not be given to acutely ill medical patients at high risk of bleeding to prevent a venous thrombosis event. High risk conditions includes active cancer; gastroduodenal ulcer in the three months prior to treatment; or a history of bronchiectasis, bleeding in the

three months prior to treatment, dual antiplatelet therapy, or pulmonary cavitation or hemorrhage.

- Do not expect to give rivaroxaban to patients with triple-positive antiphospholipid syndrome because of increased rates of recurrent thrombotic events.
- Be aware that rivaroxaban should not be given to patients with prosthetic heart valves or as an alternative to unfractionated heparin in patients with pulmonary embolism who are hemodynamically unstable or who may receive pulmonary embolectomy or thrombolysis.
- Be aware that rivaroxaban should be used cautiously during pregnancy because drug has the potential to cross the placenta, causing bleeding at any site in the fetus and/or neonate.
- Monitor patient closely for signs and symptoms of a hypersensitivity reaction because severe hypersensitivity reactions have occurred following rivaroxaban therapy.
- Be aware that manufacturer guidelines should be followed when patient is switching from or to other anticoagulants. For example, when patient is switching from warfarin to rivaroxaban therapy, expect warfarin to be discontinued and rivaroxaban started when the International Normalized Ratio (INR) is below 3. For patients currently receiving an anticoagulant other than warfarin, such as low-molecular-weight heparin or nonwarfarin oral anticoagulant, expect to start rivaroxaban therapy within 2 hours of the next scheduled evening administration of the drug, and plan to omit administration of the other anticoagulant, as ordered. For unfractionated heparin being administered by continuous infusion, expect to stop the infusion and start rivaroxaban therapy at the same time. For patients currently taking rivaroxaban and transitioning to an anticoagulant with rapid onset, expect rivaroxaban to be discontinued and the first dose of the other anticoagulant given at the time the next rivaroxaban would have been given.
- Administering rivaroxaban via a nasogastric tube or gastric feeding tube requires tablets to be crushed and suspended in 50 ml of water. Following administration, enteral feeding should be given immediately.
- Expect rivaroxaban to be discontinued if acute renal failure occurs.

**WARNING** Monitor patient closely for bleeding as rivaroxaban therapy may cause life-threatening bleeding. Expect to administer the antidote available to reverse the anti-factor Xa activity of rivaroxaban if bleeding is significant.

- Expect rivaroxaban to be discontinued 24 hours before an invasive procedure or surgery, if possible and restarted after adequate hemostasis has been established after the invasive surgery or procedure.
- Know that if patient has an epidural catheter inserted, it should not be removed any earlier than 18 hours for younger patients (less than 45 years) and 26 hours for older patients (60 years and over) after the last rivaroxaban dose was administered. Obtain specific guidelines for catheter removal from prescriber for patients between 45 and 60 years of age. The next rivaroxaban dose should not be administered any earlier than 6 hours after the removal of the catheter because an epidural or spinal hematoma can occur and can result in long-term or permanent paralysis. If traumatic puncture occurs, know that rivaroxaban should be withheld for 24 hours.
- Be aware that if rivaroxaban is discontinued and adequate alternative anticoagulation is not present, the risk for thrombosis increases. Monitor patient closely.

## **PATIENT TEACHING**

- Emphasize the importance of taking rivaroxaban exactly as prescribed.
- Instruct patient taking 15- or 20-mg tablets to take with food; 10-mg tablets do not need to be taken with food. For patient unable to swallow tablets, tell patient to crush tablets and mix with applesauce immediately prior to taking and then follow with food.
- Tell patient not to stop taking rivaroxaban without first consulting prescriber.
- Instruct patient with atrial fibrillation to take the drug with the evening meal.
- Advise patient to report any unusual bleeding or bruising to the prescriber. Inform patient that it may take longer for him to stop bleeding and to take bleeding precautions, such as avoiding the use of a razor and using a soft-bristle toothbrush.
- Tell patient to alert all prescribers to use of rivaroxaban therapy before any invasive procedure, including dental work, is scheduled.
- Instruct patient who has had spinal anesthesia or puncture to watch for back pain, muscle weakness, numbness (especially in the lower limbs), stool or urine incontinence, or tingling. If present, stress importance of notifying prescriber immediately.

- Caution patient not to take any prescription or nonprescription medication, including over-the-counter and herbal medicines, without first consulting with prescriber.
- Advise female patient to notify prescriber immediately if pregnancy is suspected or known.

**rivastigmine**

**Exelon Patch**

**rivastigmine tartrate**

**Exelon**

## **Class and Category**

*Pharmacologic class:* Cholinesterase inhibitor

*Therapeutic class:* Antidementia

## **Indications and Dosages**

- *To treat mild-to-moderate Alzheimer's-type dementia*

### **CAPSULES, ORAL SOLUTION**

**Adults.** *Initial:* 1.5 mg twice daily with morning and evening meals. Dosage increased by 3 mg daily every 2 wk, as needed. *Maximum:* 6 mg twice daily with morning and evening meals.

- *To treat mild, moderate, and severe Alzheimer's disease*

## TRANSDERMAL

**Adults.** *Initial:* 4.6 mg/24 hr. After 4 wk, increased to 9.5 mg/24 hr. When therapeutic effect begins to decrease in and with at least 4 wk from last dosage increase, dosage increased to 13.3 mg/24 hr. *Maximum:* 13.3 mg/24 hr.

- *To treat mild-to-moderate dementia in Parkinson's disease*

## CAPSULES, ORAL SOLUTION

**Adults.** *Initial:* 1.5 mg twice daily with morning and evening meals. Dosage increased by 3 mg daily every 4 wk, as needed. *Maximum:* 6 mg twice daily with morning and evening meals.

## TRANSDERMAL

**Adults.** *Initial:* 4.6 mg/24 hr. After 4 wk, increased to 9.5 mg/24 hr. When therapeutic effect begins to decrease, dosage increased to 13.3 mg/24 hr. *Maximum:* 13.3 mg/24 hr.

- *To convert patient from oral to transdermal rivastigmine therapy*

## TRANSDERMAL

**Adults.** If total oral dosage was less than 6 mg daily, use 4.6 mg/24 hr, with first transdermal patch applied the day after the last oral dose. If total oral dosage was 6 to 12 mg daily, use 9.5 mg/24 hr, with first transdermal patch applied the day after the last oral dose.

***DOSAGE ADJUSTMENT*** If patient develops adverse effects (such as nausea or vomiting), treatment should be stopped for several doses, as prescribed and restarted at the same or next lower dose level. For patient with mild-to-moderate

hepatic impairment, 4.6 mg/24 hr patch used for both initial and maximum dose. For patients with low body weight of less than 50 kg (110 lb) and experiencing excessive nausea and vomiting, maintenance dose kept at 4.6 mg/24 hr

## **Mechanism of Action**

May slow the decline of cognitive function by increasing acetylcholine concentration at cholinergic transmission sites. This action prolongs and exaggerates the effects of acetylcholine that are otherwise blocked by toxic levels of anticholinergics. Cognitive decline is partially related to cholinergic deficits along neuronal pathways projecting from the basal forebrain to the cerebral cortex and hippocampus that are involved in attention, cognition, learning, and memory.

## **Contraindications**

History of application-site reactions suggestive of allergic contact dermatitis (for patch form); hypersensitivity to carbamate derivatives, rivastigmine, or their components

## **Interactions**

### **DRUGS**

*anticholinergics*: Possibly decreased effectiveness of anticholinergics

*beta blockers*: Possible additive bradycardic effects resulting in syncope

*metoclopramide*: Increased risk of additive extrapyramidal adverse reactions.

*other cholinomimetic drugs:* Possibly increased cholinergic effects

## Adverse Reactions

**CNS:** Aggression, anxiety, asthenia, confusion, depression, dizziness, extrapyramidal movements, fatigue, fever, hallucinations, headache, insomnia, malaise, nightmares, **seizures**, somnolence, tremor worsening of Parkinsonism

**CV:** Hypertension, tachycardia

**EENT:** Rhinitis

**GI:** Abdominal pain, anorexia, constipation, diarrhea, duodenal ulcers, elevated liver enzymes, flatulence, **hepatitis**, indigestion, nausea, vomiting

**GU:** UTI

**SKIN:** Allergic or disseminated dermatitis, increased sweating, reaction at patch application site (papule or vesicle formation, pruritus, redness, swelling), **Stevens-Johnson syndrome**, urticaria

**Other:** Dehydration, flu-like symptoms, weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

**WARNING** Be aware that rivastigmine should be started at lowest recommended dosage and adjusted to effective maintenance dosage because initial therapy at high dosage can cause serious adverse GI reactions, including anorexia, nausea, and weight loss. Also, a higher than recommended starting dosage may cause severe vomiting and possibly esophageal rupture. If treatment is interrupted for longer than several days, expect to restart at lowest recommended dosage.

- Be aware that drug shouldn't be stopped abruptly because doing so may increase behavioral disturbances and precipitate a further decline in cognitive function.
- Monitor respiratory status of patients with pulmonary disease, including asthma, chronic bronchitis, and emphysema, because rivastigmine has a weak affinity for peripheral cholinesterase, which may increase bronchoconstriction and bronchial secretions.
- Monitor patient for adequate urine output because cholinomimetics, such as rivastigmine, may induce or exacerbate bladder or urinary tract obstruction.
- Monitor patients with Parkinson's disease for exaggerated parkinsonian symptoms, which may result from drug's increased cholinergic effects on CNS.

**WARNING** Monitor patient closely for hypersensitivity skin reactions regardless of route of administration. If suspected, notify prescriber, and expect drug to be discontinued.

## PATIENT TEACHING

- Explain to patient and family that rivastigmine can't cure Alzheimer's or Parkinson's disease but may slow the progressive deterioration of memory and improve patient's ability to perform activities of daily living.

- Teach patient and family how to administer oral solution, if prescribed, emphasizing need to use the oral dosing syringe provided. Explain that dose may be swallowed directly from the syringe or mixed into a small glass of cold fruit juice, soda or water; stirred; and then drunk.
- Explain that oral drug should be taken with food to reduce adverse GI effects.
- Instruct patient or caregiver to apply transdermal patch to clean, dry, hairless, intact skin in a location, such as the back, that won't be rubbed by tight clothing and won't be affected by cream, lotion, or powder. Tell patient to remove the old patch before applying a new one and to use a new application site daily. Caution against using the same site within 14 days.
- Tell patient applying transdermal patch to press patch firmly against skin until the edges stick well. Reassure patient that patch may be worn while bathing or swimming.
- Instruct a family member to supervise patient's use of rivastigmine.
- Urge caregiver to contact prescriber and to withhold drug if patient stops taking it for more than several days.
- Emphasize importance of inspecting skin for signs of an allergic reaction, such as presence of hives, itching, rash, or redness. If present, instruct patient or family to notify prescriber, as drug will have to be discontinued.

## rizatriptan benzoate

**Maxalt, Maxalt-MLT**

### **Class and Category**

*Pharmacologic class:* Selective serotonin receptor agonist

*Therapeutic class:* Antimigraine

### **Indications and Dosages**

- *To relieve acute migraine headache*

## **DISINTEGRATING TABLETS, TABLETS**

**Adults.** 5 or 10 mg when migraine headache starts; repeated 2 hr later, as needed. Additional doses spaced at least 2 hr apart, if needed.

*Maximum:* 30 mg daily.

**Children age 6 to 17 years weighing 40 kg (88 lb) or more.** 10 mg as a single dose when migraine headache starts.

**Children age 6 to 17 years weighing less than 40 kg (88 lb).** 5 mg as a single dose when migraine headache starts.

***DOSAGE ADJUSTMENT*** For adults taking propranolol, initial dosage reduced to 5 mg, and maximum dosage reduced to 15 mg daily. For pediatric patients weighing 40 kg (88 lb) or more taking propranolol, dosage reduced to 5 mg as a single dose. For pediatric patients weighing less than 40 kg (88 lb) taking propranolol, rizatriptan should not be used.

## **Mechanism of Action**

Binds to selective 5-hydroxytryptamine receptor sites on cerebral blood vessels, causing vessels to constrict. This may decrease the characteristic pulsing sensation and thus relieve the pain of migraine headaches. Rizatriptan may also relieve pain by inhibiting the release of proinflammatory neuropeptides and reducing transmission of trigeminal nerve impulses from sensory nerve endings during a migraine attack.

## **Contraindications**

Basilar or hemiplegic migraine, coronary artery vasospasm including Prinzmetal's angina, history of stroke or transient ischemic attack, hypersensitivity to rizatriptan or its components, ischemic bowel disease, ischemic coronary artery disease or other significant underlying cardiovascular disease, uncontrolled hypertension, use within 14 days of MAO inhibitor therapy, use within 24 hours of ergotamine-containing or ergot-type drugs or other serotonin-receptor agonists

## Interactions

### DRUGS

*ergot-containing drugs*: Prolonged vasospastic reactions  
*MAO inhibitors, propranolol*: Increased blood rizatriptan level

*selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, other triptans*: Increased risk of serotonin syndrome  
*serotonin-receptor agonists*: Additive vasospastic effects

## Adverse Reactions

**CNS**: Altered temperature sensation, anxiety, asthenia, ataxia, chills, confusion, depression, disorientation, dizziness, dream disturbances, drowsiness, euphoria, fatigue, hangover, headache, hypoesthesia, insomnia, mental impairment, nervousness, paresthesia, somnolence, tremor, vertigo

**CV**: **Bradycardia**, chest pain, hot flashes, hypertension, palpitations, tachycardia

**EENT**: Blurred vision; burning eyes; dry eyes, mouth, and throat; earache; eye irritation; lacrimation; nasal

congestion and irritation or pain; **pharyngeal edema**; pharyngitis; tinnitus; tongue swelling

**GI:** Abdominal distention, constipation, diarrhea, dysphagia, flatulence, heartburn, indigestion, nausea, thirst, vomiting

**GU:** Menstrual irregularities, polyuria, urinary frequency

**MS:** Arthralgia; dysarthria; muscle spasms, stiffness, or weakness; myalgia

**RESP:** Dyspnea, upper respiratory tract infection, wheezing

**SKIN:** Diaphoresis, flushing, pruritus, rash, urticaria

**Other:** **Angioedema**, dehydration

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-986-8999 or <http://www.merckpregnancyregistries.com/maxalt.html>.
- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use rizatriptan cautiously in patients with hepatic or renal dysfunction because of impaired drug excretion or metabolism. Monitor patient's BUN and serum creatinine levels and liver enzymes, as appropriate.

- Also use cautiously in patients with peripheral vascular disease because drug may cause vasospastic reactions, leading to colonic and vascular ischemia with abdominal pain and bloody diarrhea. Assess bowel sounds and peripheral circulation frequently during therapy.
- Assess patient's cardiovascular status and institute continuous ECG monitoring, as ordered, immediately after giving rizatriptan in patients with cardiovascular risk factors, because of possible asymptomatic cardiac ischemia.
- Monitor blood pressure regularly in patients with hypertension because rizatriptan may increase blood pressure.

**WARNING** Monitor patient closely for serotonin syndrome if she is taking rizatriptan along with a selective serotonin reuptake inhibitor or serotonin norepinephrine reuptake inhibitor. Notify prescriber immediately if the patient exhibits agitation, coma, diarrhea, hallucinations, hyperreflexia, hyperthermia, incoordination, labile blood pressure, nausea, tachycardia, or vomiting, as serotonin syndrome can be life-threatening. Provide supportive care.

## **PATIENT TEACHING**

- Instruct patient taking rizatriptan-disintegrating tablets to remove tablet from blister pack with dry hands just before taking, to place tablet on tongue, and to allow it to dissolve and be swallowed with saliva.
- Advise phenylketonuric patient not to use disintegrating tablet form because it contains phenylalanine.
- Instruct patient to seek emergency care immediately if cardiac symptoms, such as chest pain, occur after administration.
- Caution patient about possible adverse CNS reactions, and advise her to avoid potentially hazardous activities until drug's CNS effects are known.
- Urge patient to inform all prescribers of rizatriptan therapy because serious drug interactions may occur.

# roflumilast

## Daliresp

### Class and Category

*Pharmacologic class:* Selective phosphodiesterase 4 inhibitor

*Therapeutic class:* Antipulmonic obstructive agent

### Indications and Dosages

- *To reduce the risk of COPD exacerbations in patients with severe COPD associated with chronic bronchitis and a history of exacerbations*

### TABLETS

**Adults.** *Initial:* 250 mcg once daily for 4 wk, then increased to maintenance dose of 500 mcg daily.

### Mechanism of Action

Increases intracellular cyclic AMP in lung cells by inhibiting a major cyclic AMP-metabolizing enzyme in lung tissue to improve pulmonary function

### Contraindications

Hypersensitivity to roflumilast or its components, moderate to severe liver impairment

# Interactions

## DRUGS

*CYP450 inducers such as carbamazepine, phenobarbital, phenytoin, rifampicin:* Decreased effectiveness of roflumilast

*CYP450 inhibitors or dual inhibitors (both CYP1A2 and CYP3A4), such as cimetidine, enoxacin, erythromycin, fluvoxamine, ketoconazole; oral contraceptives containing gestodene and ethinyl estradiol:* Increased roflumilast exposure with increased risk of adverse effects

## Adverse Reactions

**CNS:** Anxiety, depression, dizziness, headache, insomnia, **suicidal ideation**, tremor

**CV:** **Atrial fibrillation**

**EENT:** Rhinitis, sinusitis

**ENDO:** Gynecomastia

**GI:** Abdominal pain, **acute pancreatitis**, anorexia, diarrhea, dyspepsia, gastritis, nausea, vomiting

**GU:** **Acute renal failure**, UTI

**MS:** Back pain, muscle spasms

**SKIN:** Rash, urticaria

**Other:** **Angioedema**, flu-like symptoms, weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Drug should not be used during labor and delivery as animal studies showed drug disrupts the labor and delivery process.

## LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

- Monitor effectiveness of roflumilast to reduce COPD exacerbations.
- Watch patient closely for suicidal tendencies because roflumilast has been associated with an increase in psychiatric adverse reactions, such as depression and insomnia, as well as suicidal ideation.
- Monitor patient's weight and notify prescriber if significant weight loss occurs.

## PATIENT TEACHING

- Tell family or caregiver to monitor patient for suicidal tendencies because drug may worsen depression during roflumilast and increase suicidal thinking.
- Warn patient that roflumilast is not a bronchodilator and should not be used to relieve acute bronchospasm.
- Inform women wishing to breastfeed their infants that drug is excreted in breast milk and breastfeeding should not be done.

**rolapitant**

**Varubi, Varubi IV**

---

## Class and Category

*Pharmacologic class:* Substance P and neurokinin-1 receptor antagonist

*Therapeutic class:* Antiemetic

## Indications and Dosages

- *Adjunct to prevent delayed nausea and vomiting associated with emetogenic cancer chemotherapy*

### **TABLETS**

**Adults receiving cisplatin-based highly emetogenic cancer chemotherapy; adults receiving moderately emetogenic cancer chemotherapy and combinations of anthracycline and cyclophosphamide.** 180 mg within 2 hr prior to chemotherapy in combination with dexamethasone and a 5-HT<sub>3</sub> receptor antagonist.

### **I.V. INFUSION**

**Adults receiving cisplatin-based highly emetogenic cancer chemotherapy; adults receiving moderately emetogenic cancer chemotherapy and combinations of anthracycline and cyclophosphamide.** 166.5 mg infused over 30 min within 2 hr prior to chemotherapy in combination with dexamethasone and a 5-HT<sub>3</sub> receptor antagonist.

## Mechanism of Action

Crosses the blood-brain barrier to occupy brain P/NK1 receptors, which prevents nerve transmission of signals

that cause nausea and vomiting.

## Contraindications

Concurrent therapy with CYP2D6 substrates with a narrow therapeutic index such as pimozide and thioridazine, hypersensitivity to rolapitant or its components (including soybean oil)

## Interactions

### DRUGS

*dextromethorphan and other CYP2D6 substrates:* May increase plasma concentrations of these drugs  
*digoxin and other P-gp substrates with a narrow therapeutic index; irinotecan, methotrexate, topotecan, and other BCRP substrates with a narrow therapeutic index:* Increased plasma concentrations of these drugs, which increases risk of adverse reactions  
*pimozide, thioridazine, and other CYP2D6 substrates with a narrow therapeutic index:* Increased plasma concentrations of these drugs, which can result in QT prolongation and torsades de pointes  
*rifampin and other strong CYP3A4 inducers:* Decreased plasma concentrations and effectiveness of rolapitant

## Adverse Reactions

**CNS:** Dizziness

**CV:** Chest pain, **hypotension**

**EENT:** Stomatitis

**GI:** Abdominal pain, anorexia, dyspepsia, hiccups

**GU:** UTI

**HEME:** Anemia, **neutropenia**

**RESP:** Dyspnea, wheezing

**SKIN:** Flushing, pruritus, urticaria

**Other:** **Anaphylaxis** including shock, **angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Drug may impair fertility in females in a reversible fashion according to animal studies.

## Nursing Considerations

- Know that rolapitant should not be given to patients with severe hepatic impairment but in the event its use cannot be avoided, monitor patient closely for rolapitant-related adverse reactions.
- Administer rolapitant within 2 hours of chemotherapy. Make sure dexamethasone and a 5-HT<sub>3</sub> receptor antagonist has also been prescribed and is on hand ready to be given, as directed.
- Be aware that intravenous form of rolapitant does not require reconstitution or refrigeration. Once stopper is punctured in drug vial, use immediately. Do not add any diluents or medications directly into vial. Infuse over 30 minutes.

**WARNING** Monitor patient receiving rolapitant for hypersensitivity reactions that may occur within minutes during or after infusion of rolapitant injectable emulsion and can be life-threatening. If present, stop infusion immediately, notify prescriber, and be prepared to administer supportive emergency treatment, as ordered, that may include antihistamines and/or epinephrine.

## PATIENT TEACHING

- Review with patient when rolapitant is to be administered in conjunction with the patient's chemotherapy. Also, instruct patient when to take dexamethasone if it is prescribed after his chemotherapy.
- Tell patient to inform all prescribers of rolapitant therapy.
- Advise women of childbearing age that rolapitant may impair fertility.

**romosozumab-aqqg**

**Evenity**

## Class and Category

*Pharmacologic class: Monoclonal antibody*

*Therapeutic class: Anti-osteoporotic*

## Indications and Dosages

- *To treat osteoporosis in postmenopausal women at risk for fracture or who have failed or are intolerant to other available osteoporosis therapy.*

## SUBCUTANEOUS INJECTION

**Postmenopausal women.** 210 mg given by injecting two consecutive 105-mg injections once a month for 12 months.

## Mechanism of Action

Inhibits the action of sclerostin, a regulatory factor in bone metabolism, which increases bone formation and, to a lesser extent, decreases bone resorption.

## Contraindications

Hypersensitivity to romosozumab or its components, uncorrected hypocalcemia

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Asthenia, **CVA**, headache, insomnia, paresthesia

**CV:** **MI**, peripheral edema

**MS:** Arthralgia, atypical subtrochanteric and diaphyseal femoral fractures, muscle spasms, neck pain, osteonecrosis of the jaw

**SKIN:** Dermatitis, **erythema multiforme**, rash, urticaria

**Other:** **Angioedema**, antibody formation to romosozumab, **hypocalcemia**, injection-site reactions (erythema, pain)

## Childbearing Considerations

## **PREGNANCY**

Drug is not indicated for use in women of childbearing age.

## **LACTATION**

- Drug is not indicated for use in women of childbearing age.

## **Nursing Considerations**

- Know that romosozumab should not be administered to patients who have had an MI or CVA within the preceding year. Additionally, romosozumab should be discontinued if MI or stroke occurs during therapy.
- Ensure that preexisting hypocalcemia is corrected prior to initiating romosozumab therapy.
- Check to see if patient has had a routine oral exam and any abnormalities taken care of before starting romosozumab therapy because drug can cause osteonecrosis of the jaw, which could occur spontaneously with tooth extraction and/or local dental infection with delayed healing. Patients should be counseled to maintain good oral hygiene.
- Know that the monthly dose of romosozumab requires administering two separate subcutaneous injections. When removing two prefilled syringes from the carton, visually inspect the solution. It should be clear to opalescent, colorless to light yellow. Always hold prefilled syringe by the syringe barrel to remove syringe from the tray. Do not grasp the plunger rod or gray needle cap and do not remove gray needle cap until ready to inject. Allow solution to sit at room temperature for at least 30 minutes before injecting. Do not warm in any other way.
- Inject each injection for the monthly dose in two separate locations such as abdomen, outer area of upper arm, or thigh. Do not inject where skin is bruised, hard, red, or tender, and avoid injecting into areas with scars or stretch marks. When ready to inject, pull gray needle cap straight off from the first syringe and away from your body. Do not put gray needle cap back onto syringe. Insert needle and inject all the liquid subcutaneously. When done, gently lift syringe off the skin. Repeat steps with second syringe.

**WARNING** Monitor patient for hypersensitivity reactions that could be life-threatening, such as angioedema or

erythema multiforme. If signs and symptoms occur, stop romosozumab therapy and notify prescriber. Expect to provide supportive care, as ordered.

- Administer a missed dose as soon as possible and reschedule remaining monthly doses from date of the last dose.
- Monitor patient's cardiac status throughout romosozumab therapy because drug increases the risk of major adverse cardiac events. If patient develops any abnormality, notify prescriber immediately. If confirmed, expect drug to be discontinued.
- Monitor patient's calcium level throughout therapy because drug may cause hypocalcemia. Patients at greater risk are those with severe renal impairment or who are receiving dialysis. Ensure that patient is taking adequate amounts of calcium and vitamin D supplements.

## **PATIENT TEACHING**

- Inform patient that romosozumab therapy will be given monthly for 12 months and requires 2 consecutive subcutaneous injections each month.
- Instruct patient to take a calcium and vitamin supplement while taking romosozumab.
- Tell patient to alert prescriber if dull, aching thigh pain occurs or if new or unusual groin, hip, or thigh pain is present.

**WARNING** Instruct patient on the signs and symptoms of a heart attack or stroke. Urge patient to seek immediate medical attention if present.

**WARNING** Review signs and symptoms of an allergic reaction, such as hives, rash, swelling or difficulty swallowing, or unusual skin condition. Tell patient to seek emergency care if severe.

- Tell patient to inform dentist of romosozumab therapy before any dental work is done, especially invasive dental procedures.

# ropinirole hydrochloride

## Requip, Requip XL

### Class and Category

*Pharmacologic class:* Nonergot alkaloid dopamine agonist

*Therapeutic class:* Antiparkinsonian

### Indications and Dosages

➤ *To treat signs and symptoms of Parkinson's disease*

#### **TABLETS**

**Adults.** *Initial:* 0.25 mg three times a day. Dosage titrated upward every wk according to the following schedule: 0.25 mg three times a day in wk 1; 0.5 mg three times a day in wk 2; 0.75 mg three times a day in wk 3; 1 mg three times a day in wk 4. After wk 4, if needed, dosage increased by 1.5 mg daily every wk up to 9 mg daily, then by 3 mg/day up to 24 mg daily. *Maximum:* 24 mg/day in three divided doses.

#### **E.R. TABLETS**

**Adults.** *Initial:* 2 mg once daily for 1 to 2 wk, increased, as needed, in increments of 2 mg/day at 1 wk or longer intervals.

*Maximum:* For patients with early Parkinson's disease, 12 mg daily or lower; for patients with advanced Parkinson's disease, 8 mg daily or lower.

**DOSAGE ADJUSTMENT** For patient with end-stage renal disease on hemodialysis, dosage titration is based on tolerability and need for efficacy; maximum total daily dose reduced to 18 mg daily.

➤ *To treat moderate to severe primary restless legs syndrome*

## TABLETS

**Adults.** *Initial:* 0.25 mg 1 to 3 hr before bedtime. Dosage increased, as needed, on day 3 to 0.5 mg and then to 1 mg at beginning of week 2 (day 8). If needed, dosage further increased in 0.5-mg increments every wk for 4 wk, followed by a 1 mg increase between wk 6 and 7, if needed.

*Maximum:* 4 mg daily.

**DOSAGE ADJUSTMENT** For patients with end-stage renal disease on hemodialysis, dosage titration of immediate-release tablets, is based on tolerability and need for efficacy, with recommended maximum total daily dose reduced to 18 mg/day for treatment of Parkinson's disease and 3 mg daily for patients with restless legs syndrome receiving regular dialysis. For patients with end-stage renal disease on hemodialysis and taking extended-release tablets, initial dose is 2 mg daily with dosage titration based on tolerability and need for efficacy, with recommended maximum total daily dose limited to 18 mg/day in patients receiving regular dialysis.

## Mechanism of Action

Directly stimulates postsynaptic dopamine type 2 (D<sub>2</sub>) receptors within the brain and acts as an agonist at peripheral D<sub>2</sub> receptors. These actions inhibit the firing of striatal cholinergic neurons, thus helping to control

alterations in voluntary muscle movement (such as rigidity and tremors) associated with Parkinson's disease.

## Contraindications

Hypersensitivity to ropinirole or its components

## Interactions

### DRUGS

*ciprofloxacin, other CYP1A2 inhibitors:* Altered drug clearance and increased blood level of immediate-release tablets ropinirole

*CYP1A2 inducers; dopamine antagonists such as butyrophenones, metoclopramide, phenothiazines, thioxanthenes:* Possibly decreased effectiveness of ropinirole

*ethinyl estradiol (higher doses associated with hormone replacement therapy):* Possibly reduced clearance of ropinirole

### ACTIVITIES

*smoking:* Increased clearance of ropinirole with decreased effectiveness

## Adverse Reactions

**CNS:** Abnormal dreaming, amnesia, anxiety, asthenia, compulsive behaviors, confusion, dizziness, dyskinesia, falling asleep during activities of daily living, fatigue, hallucinations, headache, hypoesthesia, hypokinesia, insomnia, malaise, nervousness, neuralgia, paresis,

paresthesia, psychotic-like behaviors, rigors, somnolence, syncope, transient ischemic attack, tremor, vertigo

**CV:** **Acute coronary syndrome**, angina, **bradycardia**, **cardiac failure**, chest pain, hypertension, **MI**, orthostatic hypotension, palpitations, peripheral edema, **sick sinus syndrome**, tachycardia

**EENT:** Abnormal vision, diplopia, dry mouth, increased salivation, nasal congestion, nasopharyngitis, rhinitis, toothache

**GI:** Abdominal pain, constipation, diarrhea, dyspepsia, dysphagia, flatulence, **gastric hemorrhage**, gastroenteritis, indigestion, **intestinal obstruction**, **ischemic hepatitis**, nausea, **pancreatitis**, vomiting

**GU:** Elevated BUN level, erectile dysfunction, pyuria, urinary incontinence, UTI

**HEME:** Anemia

**MS:** Arthralgia; arthritis; back pain; exacerbation of restless leg syndrome limb pain; muscle cramps, spasms, or stiffness; myalgia; neck pain; osteoarthritis; tendinitis

**RESP:** **Asthma**, bronchitis, cough, dyspnea, upper respiratory tract infection

**SKIN:** Diaphoresis, flushing, hot flashes, **melanoma**, night sweats, pruritus, rash, urticaria

**Other:** **Angioedema**, elevation of serum creatine phosphokinase (CPK), flu-like symptoms, viral infection, weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Inhibition of lactation is likely because drug inhibits the secretion of prolactin.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Expect to reassess patient for excessive sedation periodically during therapy. Excessive, acute drowsiness may arise as late as 1 year after starting therapy.

- When ropinirole is given as adjunct to levodopa, expect concurrent dosage of levodopa to be gradually decreased as tolerated.
- Expect to stop ropinirole gradually over 7 days, as follows: over first 4 days, reduce from three times a day to twice daily; during last 3 days, reduce to once daily, followed by complete withdrawal of drug.

**WARNING** Watch for altered mental status during drug withdrawal. Rapid dose reduction may lead to a symptom complex resembling neuroleptic malignant syndrome that includes altered level of consciousness, autonomic instability, fever, and muscle rigidity.

- Watch for orthostatic hypotension, especially in patient with early Parkinson's disease. Orthostatic hypotension can occur more than 4 weeks after start of therapy or after a dosage reduction because ropinirole may impair systemic regulation of blood pressure.
- Monitor patient for hallucinations, especially if patient has Parkinson's disease, is elderly, or takes levodopa.
- Monitor patient for worsening of pre-existing dyskinesia; ropinirole may potentiate dopaminergic adverse effects of levodopa.
- Avoid giving CNS depressants, other CNS-interacting drugs, and sleep aids during ropinirole therapy because they increase the risk of

somnolence.

- Assess patient for skin changes regularly because risk of melanoma is higher in patients with Parkinson's disease. It isn't clear whether this results from disease or from the drugs used to treat it.

## **PATIENT TEACHING**

- Inform patient with Parkinson's disease that ropinirole helps to improve muscle control and movement but doesn't cure Parkinson's disease.
- Encourage patient to take ropinirole with food to decrease risk of adverse GI effects. Tell her not to chew, crush, or divide extended-release tablets but to swallow them whole.
- Caution patient not to stop taking ropinirole abruptly. If concerns arise over ropinirole therapy, encourage her to speak with prescriber.
- Instruct patient to notify prescriber if allergic reactions occur, such as hives, itching, or rash. If facial swelling or difficulty breathing occurs, tell patient to seek immediate emergency treatment.
- Caution patient to avoid hazardous activities until CNS effects of drug—including sedation—are known.
- Tell the patient that if she falls asleep during normal activities, she should notify prescriber.
- Urge patient to avoid consuming alcohol and other sedating drugs (such as sleep aids) during therapy because they may increase drug's CNS depressant effects.
- Urge patient to stand up slowly from a lying or sitting position to avoid feeling dizzy, faint, nauseated, or sweaty.
- Explain to patient with restless legs syndrome that symptoms might appear in early morning or have an earlier onset in the evening or even the afternoon during ropinirole therapy and could be worse or spread to other limbs. Urge patient to notify prescriber if this occurs.
- Instruct patient to change positions slowly to minimize effect on blood pressure.
- Urge patient to have regular skin examinations by a dermatologist or other qualified health professional.
- Advise patient to notify prescriber about intense urges (as for gambling or sex) because dosage may have to be reduced or drug discontinued.
- Tell patient to inform all prescribers of ropinirole therapy.

- Inform patient that smoking may decrease effectiveness of ropinirole. If smoking is started or stopped during therapy, patient should notify prescriber.
- Instruct female patients wishing to breastfeed to discuss this with prescriber, as drug could inhibit lactation.

## rosiglitazone maleate

### Avandia

## Class and Category

*Pharmacologic class:* Thiazolidinedione

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *As adjunct to diet and exercise to achieve glucose control in type 2 diabetes mellitus*

### **TABLETS**

**Adults.** *Initial:* 4 mg once daily or 2 mg twice daily, increased to 8 mg once daily or 4 mg twice daily. if glucose control is inadequate after 8 to 12 wk. *Maximum:* 8 mg daily.

## Mechanism of Action

Increases tissue sensitivity to insulin. This peroxisome proliferator-activated receptor agonist regulates the transcription of insulin-responsive genes found in key

target tissues, such as adipose tissue, the liver, and skeletal muscle. Enhanced tissue sensitivity to insulin lowers the blood glucose level.

## Contraindications

Hypersensitivity to rosiglitazone or its components, New York Heart Association (NYHA) class III or IV heart failure

## Interactions

### DRUGS

*CYP2C8 inducers, such as rifampin:* Possibly decreased effects of rosiglitazone

*CYP2C8 inhibitors, such as gemfibrozil:* Possibly increased effects of rosiglitazone

## Adverse Reactions

**CNS:** **CVA**, fatigue, headache

**CV:** Angina, **congestive heart failure**, edema, hypertension, **myocardial ischemia or infarction**

**EENT:** Blurred vision, decreased visual acuity, macular edema, nasopharyngitis, sinusitis

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Diarrhea, elevated liver enzymes, **hepatotoxicity**

**HEME:** Anemia

**MS:** Arthralgia, back pain, bone fracture (especially upper arm, foot, hand)

**RESP:** Dyspnea, upper respiratory tract infection

**SKIN:** Pruritus, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, weight gain

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## REPRODUCTION

- Drug may result in unintended pregnancy in women of childbearing age who are anovulatory because drug may cause ovulation.

# Nursing Considerations

- Give rosiglitazone cautiously in patients with edema, heart failure, or hepatic impairment because of potential adverse reactions.
- Be aware that drug isn't recommended for patients with symptomatic heart failure.
- Evaluate patient's liver function before starting drug and periodically throughout therapy, as ordered. Notify prescriber about abnormalities, such as abdominal pain, anorexia, dark urine fatigue, nausea, and vomiting. Drug may have to be stopped.

**WARNING** Monitor patient for evidence of congestive heart failure—such as edema rapid weight gain, or shortness of breath—because rosiglitazone can cause fluid retention that may lead to or worsen heart failure. Notify prescriber immediately if the patient's cardiac

status deteriorates, and expect to stop the drug, as ordered.

- Monitor fasting glucose and glycosylated hemoglobin A<sub>1c</sub> levels periodically, as ordered, to evaluate rosiglitazone effectiveness.
- Be aware that drug is effective only in the presence of endogenous insulin.

## PATIENT TEACHING

- Emphasize the need to follow an exercise program and a diet control program during rosiglitazone therapy.
- Advise patient to notify prescriber immediately if she has fluid retention, shortness of breath, or sudden weight gain, because drug may need to be discontinued.
- Instruct patient to have liver enzymes checked, as ordered, about every 2 months for first year and then annually.
- Inform anovulatory premenopausal patient that drug may induce ovulation, increasing risk of pregnancy.
- Urge patient, especially women, to take precautions against falling or experiencing trauma; drug increases risk of fractures, particularly of the foot, hand, and upper arm.
- Instruct patient to notify all prescribers of rosiglitazone therapy and not to take any medication such as over-the-counter medicines, including herbal supplements and vitamins, without consulting prescriber first.

## rosuvastatin calcium

**Crestor, Ezallor Sprinkle**

## Class and Category

*Pharmacologic class:* HMG-CoA reductase inhibitor

*Therapeutic class: Antilipemic*

## Indications and Dosages

- *As adjunct to treat hyperlipidemia, mixed dyslipidemia, hypertriglyceridemia, and primary dysbetalipoproteinemia (type III hyperlipoproteinemia); to slow the progression of atherosclerosis; to prevent primary cardiovascular disease (reduce the risk of myocardial infarction, stroke, or need for arterial revascularization procedures) in patients without clinically evident CAD but with increased risk factors of cardiovascular disease such as age (men 50 years and over; women 60 years and over), hsCRP of 2 mg/l or greater, and the presence of at least one additional cardiovascular disease risk factor such as hypertension, low HDL-C, smoking, or a family history of premature CAD*

### **TABLETS (CRESTOR)**

**Adults.** *Initial:* 10 to 20 mg daily, increased every 2 to 4 wk, as needed. *Maximum:* 40 mg daily.

- *To treat homozygous familial hypercholesterolemia*

### **TABLETS (CRESTOR)**

**Adults.** *Initial:* 20 mg daily, increased every 2 to 4 wk, as needed. *Maximum:* 40 mg daily.

**Children ages 7 to 17.** 20 mg once daily.

**Children ages 7 to 17.** 20 mg daily.

- *To treat pediatric heterozygous familial hypercholesterolemia*

### **TABLETS (CRESTOR)**

**Children ages 10 to 17.** 5 to 20 mg daily, increased every 4 wk, as needed. *Maximum:* 20 mg daily.

**Children ages 8 to less than 10.** 5 to 10 mg daily, increased every 4 wk, as needed. *Maximum:* 10 mg daily.

- *As adjunct to treat hypertirgiyceridemia, primary dysbetalipoproteinemia (type III hyperlipoproteinemia)*

## **CAPSULES (EZALLOR SPRINKLE)**

**Adults.** *Initial:* 10 to 20 mg once daily, increased as needed. *Maximum:* 40 mg once daily.

- *As adjunct to treat homozygous familial hypercholesterolemia*

## **CAPSULES (EZALLOR SPRINKLE)**

**Adults.** *Initial:* 20 mg once daily, increased as needed. *Maximum:* 40 mg once daily.

***DOSAGE ADJUSTMENT*** For patients taking cyclosporine, dosage shouldn't exceed 5 mg daily. For Asian patients, initial dosage limited to 5 mg daily. For patients taking combined atazanavir and ritonavir, lopinavir and ritonavir, gemfibrozil, or simeprevir or for patients with severe renal impairment (creatinine clearance less than 30 ml/min) not on hemodialysis, initial dosage reduced to 5 mg daily with maintenance dose not to exceed 10 mg daily.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	Unknown	3–5 hr	Unknown

## **Mechanism of Action**

Cholesterol and triglycerides circulate in the blood as part of lipoprotein complexes. Rosuvastatin inhibits the enzyme 3-hydroxy-3-methylglutaryl-coenzyme A (HMG-CoA)

reductase. This inhibition reduces lipid levels by increasing the number of hepatic low-density lipoprotein (LDL) receptors on the cell surface to increase uptake and catabolism of LDL. It also inhibits hepatic synthesis of very-low-density lipoprotein (VLDL), which decreases the total number of VLDL and LDL particles.

## Contraindications

Active liver disease, breastfeeding, hypersensitivity to rosuvastatin or its components, pregnancy, unexplained persistent elevations of serum transaminase levels

## Interactions

### DRUGS

*antacids*: Decreased blood rosuvastatin level if given within 2 hours of rosuvastatin

*atazanavir/ritonavir, cyclosporine, gemfibrozil, lopinavir/ritonavir, other lipid-lowering drugs, simeprevir*:

Increased rosuvastatin level and risk of myopathy

*colchicine*: Increased risk of myopathy, including rhabdomyolysis

*fenofibrates*: Possibly increased risk of myopathy

*niacin (equal to or greater than 1 g/day)*: Increased risk of skeletal muscle effects

*warfarin*: Increased INR

## Adverse Reactions

**CNS**: Asthenia, cognitive impairment, confusion, depression, dizziness, headache, hypertonia, insomnia, memory loss, nightmares, paresthesia, peripheral neuropathy

**CV:** Chest pain, hypertension, peripheral edema

**EENT:** Pharyngitis, rhinitis, sinusitis

**ENDO:** Elevated glycosylated hemoglobin levels, gynecomastia, hyperglycemia, thyroid function abnormalities

**GI:** Abdominal pain, constipation, diarrhea, elevated liver enzymes, gastroenteritis, **hepatic failure**, **hepatitis**, jaundice, nausea, **pancreatitis**

**GU:** **Acute renal failure**, proteinuria, UTI

**HEME:** **Thrombocytopenia**

**MS:** Arthralgia, arthritis, back pain, immune-mediated necrotizing myopathy, myalgia, myopathy, **rhabdomyolysis**

**RESP:** Bronchitis, increased cough, **interstitial lung disease**

**SKIN:** Rash, urticaria

**Other:** **Angioedema**, flu-like symptoms, generalized pain, infection

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Drug is contraindicated in pregnant women. Drug should be discontinued as soon as pregnancy is known.

### LACTATION

- Drug is present in breast milk.
- Drug is contraindicated in women who are breastfeeding.

### REPRODUCTION

- Advise women of childbearing age to use effective contraception during drug therapy.

## **Nursing Considerations**

- Use rosuvastatin cautiously in patients who consume large quantities of alcohol or who have a history of liver disease, because drug is contraindicated in patients with active liver disease or unexplained persistent elevations of transaminase levels.
- Also use cautiously in patients with risk factors for myopathy, such as advanced age, hypothyroidism, or renal impairment.
- Administer capsule form to patients who cannot swallow the capsule by opening capsule and carefully emptying the granules onto one teaspoon of applesauce. Administer immediately, cautioning patient not to chew it and to swallow it immediately. For nasogastric tube administration empty contents of capsule into a 60 ml catheter tipped syringe and add 40 ml of water. Replace the plunger and shake the syringe vigorously for 15 seconds. Attach syringe to the nasogastric tube and deliver the contents of the syringe. Afterwards, flush the nasogastric tube with 20 ml of additional water.
- If ALT or AST levels increase to more than three times the normal range, expect dosage to be reduced or drug discontinued.
- Monitor serum lipoprotein level, as ordered, to evaluate response to therapy.
- Expect rosuvastatin to be discontinued if patient develops markedly elevated creatinine kinase levels, or if myopathy is diagnosed or suspected. Drug may be temporarily withheld if patient develops any condition that may be related to myopathy or that predisposes her to renal failure, such as hypotension; major surgery; sepsis; severe electrolyte, endocrine, or metabolic disorders; trauma, or uncontrolled seizures.
- Obtain baseline liver enzymes and expect to monitor them thereafter, as indicated. Notify prescriber if proteinuria or hematuria appears in patient's routine urinalysis, because rosuvastatin dosage may need to be reduced.

## **PATIENT TEACHING**

- Encourage patient to follow a low-fat, low-cholesterol diet.

- Tell patient who takes antacids to wait at least 2 hours after taking rosuvastatin.
- Instruct patient prescribed capsule form, not to chew or crush capsules. If patient cannot swallow the capsule, it can be opened and the granules carefully emptied onto one teaspoon of applesauce. Patient should swallow mixture immediately, without chewing.
- Instruct patient to notify prescriber immediately about muscle pain, tenderness, or weakness, especially if accompanied by fever or malaise. He should also tell the prescriber if these symptoms occur even after drug is discontinued.
- Encourage patient or family to notify prescriber if patient begins to notice new onset or worsening of confusion, forgetfulness, or memory loss.
- Tell woman of childbearing age about the need to use reliable contraceptive method while taking drug. Instruct her to notify prescriber at once if she suspects she may be pregnant.
- Instruct patient with diabetes to test his blood glucose regularly and have a HbA<sub>1c</sub> level checked routinely.

## safinamide mesylate

### Xadago

## Class and Category

*Pharmacologic class:* Monoamine oxidase type B (MAO-B) inhibitor

*Therapeutic class:* Antiparkinsonian

## Indications and Dosages

- *As adjunct to levodopa/carbidopa treatment in patients with Parkinson's disease experiencing "off" episodes*

## **TABLETS**

**Adults.** *Initial:* 50 mg once daily at the same time of day, increased after 2 wk to 100 mg once daily, if needed and tolerated.

**DOSAGE ADJUSTMENT** For patient with moderate hepatic impairment, maximum dosage kept at 50 mg once daily.

## **Mechanism of Action**

Precise mechanism unknown, but by inhibiting monoamine oxidase B activity through blocking the catabolism of dopamine, it is thought this action increases dopamine levels, which in turn increase dopaminergic activity in the brain to improve Parkinson symptoms.

## **Contraindications**

Concurrent use with amphetamine and their derivatives; cyclobenzaprine; dextromethorphan; linezolid; methylphenidate; opioid drugs (*meperidine and its derivatives, methadone, propoxyphene, or tramadol*); other MAO inhibitors or other drugs that are potent inhibitors of MAOs; serotonin-norepinephrine reuptake inhibitors; St. John's wort; *tetracyclic, triazolopyridine, or tricyclic antidepressants*; hypersensitivity to safinamide or its components; severe hepatic impairment

## **Interactions**

### **DRUGS**

*amphetamine, antidepressants (tetracyclic, triazolopyridine, tricyclic), cyclobenzaprine, methylphenidate, opioid drugs, serotonin-norepinephrine*

*reuptake inhibitors, St. John's wort*: Increased risk of life-threatening serotonin syndrome

*antipsychotics, metoclopramide*: Possibly decreased effectiveness of safinamide; exacerbation of Parkinson's disease symptoms

*dextromethorphan*: Increased risk of abnormal behavior or psychosis

*isoniazid, other MAO inhibitors, other drugs that are potent inhibitors of MAO, sympathomimetics, tyramine*: Increased risk of hypertensive crisis

## Adverse Reactions

**CNS:** Anxiety, compulsive behaviors, confusion, dyskinesia, falling asleep during activities of daily living, fever, hallucinations, insomnia, lack of impulse control,

**serotonin syndrome**

**CV:** Hypertension, orthostatic hypotension

**EENT:** Gingival swelling, retinal pathology, tongue swelling

**GI:** Dyspepsia, elevated liver enzymes, nausea

**RESP:** Cough, dyspnea

**SKIN:** Rash

## Childbearing Considerations

### PREGNANCY

- It is not known if drug may cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.

- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that safinamide therapy should not be used in patients with a major psychotic disorder because drug may exacerbate the psychosis.
- Monitor patient's blood pressure closely because safinamide may cause hypertension or exacerbate existing hypertension. Be aware that although dietary restriction is not necessary during treatment with recommended doses, certain foods that are very high in tyramine (more than 150 mg) could cause severe hypertension.

**WARNING** Monitor patient closely for serotonin syndrome, a rare but serious adverse effect of MAO inhibitors such as safinamide. Signs and symptoms include agitation, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. If symptoms occur, notify prescriber immediately, expect to discontinue drug, and provide supportive care.

- Monitor patient for dyskinesia because safinamide may cause dyskinesia or exacerbate preexisting dyskinesia. Notify prescriber, because reducing the patient's daily levodopa dosage or the dosage of another dopaminergic drug may lessen the dyskinesia.
- Monitor patient for hallucinations or psychotic behavior. If present, expect dosage to be reduced or drug discontinued.
- Monitor patient for visual changes, especially in patients with a history of certain eye disorders such as active retinopathy, albinism, family history of hereditary retinal disease, inherited retinal conditions, macular or retinal degeneration, retinitis pigmentosa, or uveitis. This is because retinal degeneration and loss of photoreceptor cells may occur with safinamide therapy.

**WARNING** Be aware that 100-mg dose should be tapered to 50 mg for 1 week before safinamide is discontinued. This is because a symptom complex resembling

neuroleptic malignant syndrome, exhibited by altered consciousness, autonomic instability, elevated temperature, and muscular rigidity, has occurred with rapid dose reduction, withdrawal of, or changes in drugs that increase central dopaminergic tone.

## **PATIENT TEACHING**

- Tell patient that if a dose is missed, he should take the next dose at the same time the next day.
- Instruct patient to avoid foods very high in tyramine, because consuming such may cause very high blood pressure.
- Advise patient to avoid performing hazardous activities, as drug may cause daytime sleepiness or episodes of falling asleep during activities that require full attention, such as driving. Tell patient to notify prescriber of any such occurrence.
- Tell patient drug may cause him to experience intense urges to perform compulsive behaviors such as binge eating, gambling excessively, having sex very frequently, or spending money uncontrollably. If present, tell him to notify prescriber, as dosage may have to be reduced or drug discontinued.
- Advise patient to inform all prescribers of safinamide therapy.
- Instruct patient and family to notify prescriber if persistent, severe, or unusual adverse effects occur, including dyskinesia, hallucinations, or psychotic behavior.
- Stress importance of not stopping drug abruptly. If patient has concerns about safinamide therapy, advise him to speak with prescriber.

**salmeterol xinafoate**

**Serevent Diskus**

# Class and Category

*Pharmacologic class:* Long-acting beta<sub>2</sub> agonist (LABA)

*Therapeutic class:* Bronchodilator

# Indications and Dosages

- *To treat asthma and prevent asthma-induced bronchospasm in patients with reversible obstructive airway disease who are currently using an inhaled corticosteroid but are inadequately controlled*

## ORAL INHALATION POWDER

**Adults and children age 4 and over.** 1 inhalation (50 mcg) every 12 hr.

- *To provide maintenance treatment of bronchospasm associated with chronic obstructive pulmonary disease (COPD)*

## ORAL INHALATION POWDER

**Adults.** 1 inhalation (50 mcg) every 12 hr.

- *To prevent exercise-induced bronchospasm in patients who do not have persistent asthma or, if persistent asthma present, used in conjunction with an inhaled corticosteroid*

## ORAL INHALATION POWDER

**Adults and children age 4 and over.** 1 inhalation (50 mcg) at least 30 min before exercise. *Maximum:* No more than 1 inhalation (50 mcg) every 12 hr.

---

Route	Onset	Peak	Duration
-------	-------	------	----------

Route	Onset	Peak	Duration
Inhalation	10-20 min	3-4 hr	12 hr

## Mechanism of Action

Attaches to beta<sub>2</sub> receptors on bronchial cell membranes, stimulating the intracellular enzyme adenylate cyclase to convert adenosine triphosphate to cAMP. The resulting increase in intracellular cAMP level inhibits histamine release, relaxes bronchial smooth-muscle cells, and stabilizes mast cells.

## Contraindications

Hypersensitivity to salmeterol, its components, or to milk proteins (severe); primary treatment of status asthmaticus or other acute episodes of asthma or COPD where intensive measures are required; treatment of asthma without use of an inhaled corticosteroid

## Interactions

### DRUGS

*atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin*: Possibly increased risk of adverse cardiovascular effects

*beta blockers*: Blocked pulmonary effect of salmeterol; possibly produce severe bronchospasms

*loop or thiazide diuretics*: Increased risk of hypokalemia and potentially life-threatening arrhythmias

*MAO inhibitors, tricyclic antidepressants*: Potentiated adverse vascular effects, such as hypertensive crisis

# Adverse Reactions

**CNS:** Dizziness, fever, headache, nervousness, paresthesia, tremor

**CV:** Palpitations, tachycardia

**EENT:** Dry mouth, nose, and throat; sinus problems

**GI:** Nausea

**MS:** Arthralgia

**RESP:** Cough, **paradoxical bronchospasm**

**SKIN:** Contact dermatitis, eczema, rash, urticaria

**Other:** **Angioedema**, generalized aches and pains

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Drug use should be restricted to patients only if the benefit clearly outweighs the risk because drug may interfere with uterine contractions.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Be aware that salmeterol shouldn't be used to relieve bronchospasm quickly because of its prolonged onset of action and that patients already

taking drug twice daily shouldn't take additional doses for exercise-induced bronchospasm.

**WARNING** Be aware that a recent study suggests that asthma-related deaths may increase in asthmatics receiving salmeterol. Know that salmeterol should not be used in patients whose asthma is adequately controlled on low- or medium-dose inhaled corticosteroids and it should only be used as additional therapy for patients with asthma who are currently taking but are not adequately controlled on an inhaled corticosteroid. Salmeterol should never be used as monotherapy in the treatment of asthma. Monitor this patient population closely throughout salmeterol therapy, and notify prescriber immediately of any changes in patient's respiratory status. Expect to discontinue use as soon as possible.

- Watch for arrhythmias and changes in blood pressure after use in patients with cardiovascular disorders, including arrhythmias, hypertension, and ischemic cardiac disease, because of drug's beta-adrenergic effects.
- Monitor patient's compliance. Expect adults with poor compliance and children and adolescents who require the addition of a long-acting beta agonist such as salmeterol to be prescribed a combination product containing both an inhaled corticosteroid and a long-acting beta agonist to increase compliance.
- Be aware that Serevent Diskus delivers full dose of salmeterol in only 1 inhalation.

**WARNING** Stop salmeterol immediately and notify prescriber if patient develops paradoxical bronchospasm. Risk is greatest with first use of a new canister or vial used as an inhalant.

## **PATIENT TEACHING**

- Instruct patient to use salmeterol exactly as prescribed and not to increase dosage or frequency of use.
- Advise patient with asthma or COPD to take doses 12 hours apart for optimum effect. Caution against using drug more than every 12 hours. Also, inform patients with asthma that salmeterol must be taken with an inhaled corticosteroid because a life-threatening reaction may occur if drug is taken alone. Tell patient using salmeterol to prevent exercise-induced bronchospasm to take drug at least 30 min before exercise.
- Teach patient how to use the diskus by instructing him to slide the lever only once when preparing dose to avoid wasting doses. Advise him to exhale immediately before using the diskus and then to place mouthpiece to his lips and inhale through his mouth, not his nose. Then he should remove mouthpiece from his mouth, hold his breath for at least 10 seconds, and exhale slowly.
- Advise patient to rinse mouth with water after each dose to minimize dry mouth.
- Advise patient to store drug in a dry place away from heat and sunlight in the unopened foil pouch until ready for use. Also tell patient to discard diskus 6 weeks after removing it from overwrap or when dose indicator reads zero.

**WARNING** Instruct patient to seek immediate medical attention if after taking salmeterol he develops breathing problems, a fast or irregular heartbeat, high blood glucose level, or any persistent, severe, or unusual side effects. Tell him that if he develops a low potassium level, that should also be reported to the prescriber.

- Instruct patient to notify prescriber if he needs four or more oral inhalations of rapid-acting inhaled bronchodilator a day for 2 or more consecutive days, or if he uses more than one canister of rapid-acting bronchodilator in an 8-week period.
- Caution patient not to use other drugs to treat his underlying respiratory condition without consulting prescriber and to let all prescribers know that he takes salmeterol.
- Caution patient to keep salmeterol diskus out of the reach of children. Also tell patient not to give the diskus to other people, even if they have the same symptoms, because it may harm them.

# saquinavir mesylate

## Invirase

### Class and Category

*Pharmacologic class:* Protease inhibitor

*Therapeutic class:* Antiretroviral

### Indications and Dosages

- *As adjunct to treat human immunodeficiency viral (HIV) infection in combination with ritonavir and other antiretroviral agents*

### CAPSULES, TABLETS

**Adults and adolescents over the age of 16 who are treatment-naïve or are switching from a regimen containing delavirdine.** *Initial:* 500 mg within 2 hr after a meal twice daily in combination with ritonavir 100 mg twice daily for 7 days, then increased to 1,000 mg twice daily within 2 hr after a meal in combination with ritonavir 100 mg twice daily.

**Adults and adolescents over the age of 16 who are not treatment-naïve or are switching from another ritonavir-containing regimen or from a nonnucleoside reverse transcriptase inhibitor-based regimen not containing delavirdine or rilpivirine.** 1,000 mg within 2 hr after a meal twice daily in combination with ritonavir 100 mg twice daily.

## Mechanism of Action

Inhibits HIV protease to render the enzyme incapable of processing the Gag-Pol polyprotein precursor, which leads to the production of noninfectious immature HIV particles.

## Contraindications

Combination with drugs that both increase saquinavir plasma concentrations and prolong the QT interval or CYP3A substrates that increase saquinavir levels resulting in serious or life-threatening adverse reactions; complete atrioventricular (AV) block without implanted pacemaker or at risk for complete AV block; concomitant therapy with alfuzosin, amiodarone, atazanavir, bepridil, clarithromycin, clozapine, dasatinib, dofetilide, disopyramide, ergot derivatives, erythromycin, flecainide, halofantrine, haloperidol, lidocaine, lovastatin, lurasidone, midazolam (oral), pentamidine, phenothiazines, pimozide, propafenone, quinidine, quinine, rifampin, rilpivirine (without a washout period of at least 2 weeks), sertindole, sildenafil (for treatment of pulmonary arterial hypertension), simvastatin, sunatinib, tacrolimus, trazodone, triazolam, ziprasidone; congenital long QT syndrome; high risk for complete AV block; hypersensitivity to saquinavir or its components; refractory hypokalemia or hypomagnesemia; severe hepatic impairment

## Interactions

### DRUGS

*alfentanil, alfuzosin, amiodarone, amitriptyline, atorvastatin, benzodiazepines, bepridil, bosentan, calcium channel blockers, chlorpromazine, clarithromycin,*

*clomipramine, clozapine, colchicine, dapson, dasatinib, digoxin, disopyramide, dofetilide, ergot derivatives, erythromycin, fentanyl, flecainide, halofantrine, haloperidol, imipramine, immunosuppressants, ketoconazole, lidocaine (systemic), lovastatin, lurasidone, maraviroc, mesoridazine, midazolam, omeprazole, pimozone, propafenone, quetiapine, quinidine, quinine, rifabutin, rifampin, rilpivirine, salmeterol, sertindole, sildenafil, simvastatin, sunitinib, tacrolimus, tadalafil, thioridazine, trazodone, triazolam, vardenafil, vincamine, warfarin, ziprasidone:* Increased concentration of these drugs

*antiarrhythmics class 1A and class III, antidepressants, antihistaminics, antimicrobials, neuroleptics, PDE5 inhibitors (used for pulmonary arterial hypertension):*

Increased risk of prolonged PR and/or QT interval resulting in increased risk of ventricular arrhythmias, especially torsades de pointes

*atazanavir:* Increased concentration of atazanavir, ritonavir, and saquinavir

*carbamazepine, efavirenz, garlic capsules, nevirapine, phenobarbital, phenytoin, St. John's wort,*

*tipranavir/ritonavir:* Decreased saquinavir concentration

*corticosteroids:* Decreased concentration of saquinavir and increased concentrations of corticosteroids

*dalfopristin, quinupristin:* Possibly increased saquinavir concentration

*delavirdine, nefazodone, nelfinavir:* Increased saquinavir concentration

*ethinyl estradiol, methadone:* Decreased concentration of these drugs

*fusidic acid:* Increased concentrations of fusidic acid, ritonavir, saquinavir

*indinavir, itraconazole:* Increased concentration of both drugs

# Adverse Reactions

**CNS:** Abnormal coordination, anxiety, asthenia, confusion, depression, dizziness, fatigue, fever, headache, hypoesthesia, insomnia, **intracranial hemorrhage**, lethargy, loss of consciousness, paresthesia, peripheral neuropathy, psychotic disorder, **seizures**, somnolence, **suicidal ideation**, syncope, tremor

**CV:** Chest pain, edema, elevated LDH levels, hypertension, hypertriglyceridemia, heart murmur, **hypotension**, peripheral vasoconstriction, PR or **QT-interval prolongation**, **thrombophlebitis**

**EENT:** Sinusitis, taste distortion, tinnitus, visual impairment

**ENDO:** Diabetes mellitus (new-onset or worsening of existing condition), hyperglycemia

**GI:** Abdominal discomfort or pain, anorexia, ascites, constipation, diarrhea, dyspepsia, dysphagia, elevated liver and pancreatic enzymes, eructation, flatulence, gastritis, **gastrointestinal hemorrhage or obstruction**, **hepatitis**, hepatomegaly, hyperbilirubinemia, increased appetite, jaundice, nausea, **pancreatitis**, **portal hypertension**, vomiting

**GU:** Libido disorder, nephrolithiasis

**HEME:** Anemia including **hemolytic**, **leukopenia**, lymphadenopathy, **neutropenia**, **pancytopenia**, **thrombocytopenia**

**MS:** Arthralgia, back pain, muscle spasms, myalgia, polyarthrititis

**RESP:** Bronchitis, cough, dyspnea, pneumonia

**SKIN:** Acne, alopecia, bullous dermatitis, diaphoresis, drug eruption, dry lips or skin, eczema, erythema, papillomatosis, pruritus, rash, **severe cutaneous reaction**, **Stevens-Johnson syndrome**, urticaria

**Other:** **Acute myeloid leukemia**, dehydration, elevated alkaline phosphatase, creatine phosphokinase, flu-like symptoms, **hypersensitivity reactions**, lipodystrophy, wasting syndrome, weight gain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Be aware that saquinavir must be used in combination with ritonavir because ritonavir significantly inhibits metabolism of saquinavir to provide increased plasma saquinavir levels. However, saquinavir is not recommended for use in combination with cobicistat because dosing recommendations for this combination have not been established.
- Be aware that saquinavir capsules and tablets contain lactose and should not be taken by patients with rare hereditary problems of galactose intolerance, glucose-galactose malabsorption, or Lapp lactase deficiency.
- Be aware that if patient is unable to swallow capsules, capsules may be opened and emptied into a container. Add 15 ml of either sorbitol syrup or sugar syrup or 3 teaspoons of jam to the container. Stir with a spoon for 30 to 60 seconds. Administer the full amount prepared for each dose.

Know that the suspensions should be at room temperature before administering. Do not crush the tablet form.

- Administer ritonavir at the same time as saquinavir.
- Monitor patient closely because saquinavir interacts with many drugs. These interactions may cause serious adverse reactions that could be life-threatening or increase adverse reactions from greater exposure to saquinavir. In addition, some drug interactions can lower the therapeutic effect of saquinavir and possibly cause resistance to develop. Alert prescriber if a serious or severe toxicity occurs during treatment, as saquinavir will have to be discontinued.
- Obtain an ECG reading on all patients before starting saquinavir therapy, because of risk of PR or QT prolongation.
- Monitor patient's ECG for PR interval prolongation during therapy. Prolonged PR intervals can lead to conduction abnormalities including second- or third-degree atrioventricular block. Use caution with administering atazanavir, beta-adrenergic blockers, calcium channel blockers, or digoxin with saquinavir, because of the combined effect on the PR interval.
- Know that patients should also have ECG monitoring for QT-interval prolongation during therapy. Patients with long QT syndrome should not receive saquinavir, because of its effect on the QT interval. Risk factors for QT prolongation include presence of bradyarrhythmias, congestive heart failure, electrolyte abnormalities, or hepatic impairment. Know that hypokalemia or hypomagnesemia must be corrected before saquinavir therapy is begun. Expect to monitor patient's electrolyte levels throughout therapy. Know that saquinavir should be discontinued in any patient who develops a QT-interval prolongation greater than 20 msec over pretreatment measurement.
- Monitor patient's blood glucose levels, as new onset of diabetes mellitus, exacerbation of preexisting diabetes mellitus, and hyperglycemia have occurred with protease-inhibitor therapy such as saquinavir.
- Monitor patient with underlying chronic alcoholism, cirrhosis, hepatitis B or C, or other liver abnormalities, because portal hypertension has occurred after saquinavir therapy has been initiated. If severe hepatic dysfunction occurs, expect drug to be discontinued.
- Know that spontaneous bleeding in patients with hemophilia A and B has occurred during treatment with protease inhibitors such as saquinavir. Additional factor VIII may be required.
- Monitor patient's lipid profile, as ordered, because elevated cholesterol and/or triglyceride levels have occurred with the combination therapy of saquinavir and ritonavir.

- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including saquinavir. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

## PATIENT TEACHING

- Instruct patient who is unable to swallow capsules to open capsules and place contents into an empty container. Tell patient to add 15 ml of room-temperature sorbitol syrup or sugar syrup or 3 teaspoons of jam to the container. Stir with spoon for 30 to 60 seconds before taking the entire amount.
- Instruct patient taking tablet form of saquinavir to swallow whole and never crush the tablets.
- Tell patient to take ritonavir at the same time as saquinavir and within 2 hours after a meal.
- Tell patient with diabetes to monitor his blood glucose levels closely, as saquinavir may cause blood glucose levels to rise.
- Inform patient that saquinavir therapy may cause changes in her body appearance because of fat redistribution. Prepare her for the possibility of developing breast enlargement, central obesity, dorsocervical fat enlargement (buffalo hump), facial wasting, and peripheral wasting.
- Instruct patient to report any persistent, severe, or unusual signs and symptoms, such as dizziness, lightheadedness, or palpitations.
- Inform patients with hemophilia that saquinavir may cause spontaneous bleeding and instruct them to seek immediate medical attention if bleeding occurs.
- Stress importance of compliance with ordered laboratory studies such as lipid profile to monitor for adverse reactions.
- Advise patient to notify all prescribers of saquinavir therapy, because of potential drug interactions, and advise patient not to take over-the-counter preparations (including herbal drugs and preparations) without consulting prescriber first.

# sarecycline

**Seysara**

## Class and Category

*Pharmacologic class:* Tetracycline

*Therapeutic class:* Antibacterial

## Indications and Dosages

- *To treat inflammatory lesions of non-nodular moderate to severe acne vulgaris*

### **TABLETS**

**Adults and children age 9 and over weighing 85 kg (187 lb) to 136 kg (299.2 lb).** 150 mg once daily.

**Adults and children age 9 and over weighing 55 kg (121 lb) to 84 kg (184.8 lb).** 100 mg once daily.

**Adults and children age 9 and over weighing 33 kg (72.6 lb) to 54 kg (118.8 lb).** 60 mg once daily.

## Mechanism of Action

Although the exact mechanism of action is unknown for the treatment of acne vulgaris, the tetracycline class of antibiotics exerts a bacteriostatic effect by passing through the bacterial lipid bilayer, where it binds reversibly to 30S ribosomal subunits. This blocks the binding of aminoacyl transfer RNA to messenger RNA, thus inhibiting bacterial

protein synthesis, which may relieve the inflammation of acne vulgaris.

## Contraindications

Hypersensitivity to sarecycline, other tetracyclines, or their components

## Interactions

### DRUGS

*aluminum-, calcium-, or magnesium-containing antacids, bismuth subsalicylate, iron-containing preparations:*

Possibly altered absorption of sarecycline

*anticoagulants:* Possibly depressed plasma prothrombin activity, which may increase risk of bleeding

*oral retinoids:* Possibly additive increased risk of intracranial pressure

*penicillin:* Possible interference with bactericidal action of penicillin

*P-glycoprotein substrates such as digoxin:* Possibly increased concentrations of P-gp substrates

## Adverse Reactions

**GI:** *Clostridium difficile-associated diarrhea*, nausea

**GU:** Vulvovaginal candidiasis, vulvovaginal mycotic infection

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm such as adverse effects on skeletal and tooth development.
- The use of drug during last half of pregnancy may cause permanent discoloration of the child's teeth.
- Drug should not be used during pregnancy and should be discontinued as soon as pregnancy is known.

## LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## REPRODUCTION

- Know that drug should not be used in male patients attempting to conceive a child because animal studies have shown drug adversely affects spermatogenesis.

## Nursing Considerations

- Assess patient for signs of secondary infection, such as profuse, watery diarrhea that has occurred with nearly all antibacterial agents. If such diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused by *C. difficile*. If diarrhea occurs, notify prescriber and expect to withhold penicillin and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.
- Monitor patient for central nervous system adverse reaction such as dizziness, light-headedness, and vertigo, because although sarecycline has not been known to cause such reactions, other tetracyclines have.

**WARNING** Be aware that intracranial hypertension has occurred with the use of other tetracyclines. Monitor patient for blurred vision, headache, and papilledema. If present, notify prescriber immediately, because even though intracranial hypertension usually resolves with discontinuation of the tetracycline, vision loss may

become severe or even permanent. Women of childbearing age who are overweight are at higher risk for developing intracranial hypertension.

- Monitor patient for superinfection such as mycotic or vulvovaginal candidiasis infections. If present, notify prescriber and expect sarecycline therapy to be discontinued.

## **PATIENT TEACHING**

- Tell patient to take sarecycline therapy exactly as directed. Also stress importance of completing the full course of therapy and not skipping doses, because not doing so may decrease the effectiveness of current therapy and increase the likelihood that bacteria may develop resistance to other antibacterial drugs in the future.
- Instruct patient to take tablets with liberal amounts of fluid, to reduce risk of esophageal irritation and ulceration.
- Advise women of childbearing age that sarecycline may cause fetal harm. It may also cause permanent discoloration of teeth later on, and retardation of skeletal development in the developing fetus if exposed to the drug during the second or third trimesters of pregnancy. Suspected or known pregnancy should be reported immediately to prescriber.
- Urge patient to tell prescriber if diarrhea develops, even 2 months or more after sarecycline therapy ends.
- Caution patient not to perform hazardous activities such as driving until possible adverse reactions are known.
- Warn patient to avoid exposure to artificial or natural sunlight because photosensitivity, manifested as an exaggerated sunburn reaction, has occurred in patients taking other tetracycline products. Instruct patient to wear protective clothing and use sunscreen if natural sunlight cannot be avoided. If skin redness occurs, tell patient to report this to prescriber, as drug should be discontinued at the first sign of skin redness.
- Inform mothers wishing to breastfeed their infant that breastfeeding is not recommended during sarecycline therapy.

**WARNING** Instruct patient to report blurred vision or headaches immediately to prescriber.

---

# sarilumab

**Kevzara**

## Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Antiarthritic

## Indications and Dosages

- *To treat moderate to severe active rheumatoid arthritis in patients who have had an inadequate response or intolerance to one or more disease-modifying antirheumatic drugs (DMARDs)*

### SUBCUTANEOUS INJECTION

**Adults.** 200 mg once every 2 wk.

***DOSAGE ADJUSTMENT*** For patients who experience an absolute neutrophil count (ANC) between 500 to 1,000 cells/mm<sup>3</sup>, sarilumab withheld until ANC becomes greater than 1,000 cells/mm<sup>3</sup>. Dosage restarted at 150 mg every 2 wk and then dosage increased to 200 mg and given every 2 wk, when clinically appropriate. For patients experiencing an ANC less than 500 cells/mm<sup>3</sup>, drug discontinued. For patients who experience a low platelet count between 50,000 to 100,000 cells/mm<sup>3</sup>, drug withheld until platelets become greater than 100,000 cells/mm<sup>3</sup>. Dosage restarted at 150 mg every 2 wk and then dosage increased to 200 mg every 2 wk, when clinically appropriate. For patients experiencing a platelet count less than 50,000 cells/mm<sup>3</sup>

and confirmed with repeat testing, drug discontinued. For patients experiencing an elevated (ALT) greater than upper level normal (ULN) to three times ULN or less, dosage may have to be modified on an individual basis. For patients who experience an ALT greater than three times ULN to five times ULN or less, drug withheld until ALT is less than three times ULN. Dosage restarted at 150 mg every 2 wk and then dosage increased to 200 mg every 2 wk, as clinically appropriate. For patient experiencing an ALT greater than five times ULN, drug discontinued.

## **Mechanism of Action**

Binds to IL-6 receptors to inhibit IL-6 mediated signaling of inflammatory processes which occurs in rheumatoid arthritis. Without IL-6 mediated signaling, IL-6 as a pro-inflammatory cytokine cannot be produced by endothelial and synovial cells in joints. This helps relieve inflammation present in rheumatoid arthritis.

## **Contraindications**

Hypersensitivity to sarilumab or its components

## **Interactions**

### **DRUGS**

*atorvastatin, lovastatin, oral contraceptives:* Possibly decreased effectiveness of these drugs

*CYP450 substrates with narrow therapeutic index, such as theophylline, warfarin:* Possibly altered dosage requirements

*live vaccines:* Increased risk of vaccine-related infection

# Adverse Reactions

**CV:** Elevated cholesterol and triglyceride levels

**EENT:** Nasopharyngitis

**GI:** Elevated liver enzymes, **GI perforation**

**GU:** UTI

**HEME:** **Neutropenia**, **thrombocytopenia**

**RESP:** Upper respiratory infections

**SKIN:** Rash, urticaria

**Other:** **Anaphylaxis**; anti-sarilumab antibody formation; herpes zoster reactivation; **immunosuppression**; infections such as bacterial, invasive fungal, mycobacterial, tuberculosis, viral, or other opportunistic pathogens; injection-site erythema; pruritis, rash; **malignancies**

# Childbearing Considerations

## PREGNANCY

- Pregnancy exposure registry: 1-877-311-8972.
- Drug may affect immune system of fetus/neonate in mothers exposed to drug during pregnancy because monoclonal antibodies cross the placental barrier.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Be aware that administration of live vaccines may decrease response in infants exposed to the drug during pregnancy.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Be aware that sarilumab therapy should not be started in patients who have an elevated ALT or AST above 1.5 times the upper limit of normal, an absolute neutrophil count (ANC) less than 2,000/mm<sup>3</sup>, or platelet count less than 150,000/mm<sup>3</sup>.
- Expect patient to be tested for latent tuberculosis before sarilumab therapy is started. If result is positive, patient will need to be treated before sarilumab is initiated. In patient who has a history of active or latent tuberculosis and for whom an adequate course of treatment cannot be confirmed or results are negative, but patient has risk factors for tuberculosis infection, patient may need to be treated before beginning sarilumab therapy.
- Know that sarilumab should not be used with biological DMARDs because of increased immunosuppression and increased risk of infection.
- Be aware that sarilumab should be avoided in patients with active infections.
- Know that patients with active hepatic disease or hepatic impairment are not candidates for sarilumab therapy, because drug can have adverse effects on liver, as evidenced by elevation in liver enzymes.
- Allow prefilled syringe to sit at room temperature for 30 minutes prior to injecting drug subcutaneously. Syringe should not be warmed any other way. Inspect solution before administering. It should be clear and colorless to pale yellow. Discard if solution appears discolored, cloudy, or has particulate matter in it.

**WARNING** Monitor patient for signs and symptoms of infection because of sarilumab's immunosuppressant action. Serious and sometimes fatal infections due to bacterial, invasive fungal, mycobacterial, viral, or other opportunistic pathogens have occurred with sarilumab therapy. If infection occurs, notify prescriber, expect drug to be withheld for serious infections until infection is eradicated, and administer prescribed treatment for the infection.

- Expect to monitor patient's ALT, ANC, and platelet counts regularly. Expect dosage modifications or drug withholding until target levels are met.

- Monitor patient for hypersensitivity reactions, If present, notify prescriber, expect drug to be withheld or discontinued based upon severity of the reaction, and provide supportive care.

## **PATIENT TEACHING**

- Teach patient or caregiver how to administer a subcutaneous injection. Tell patient to rotate injection sites with each injection and not to inject into skin that is bruised, damaged, scarred, or tender.
- Instruct patient to allow prefilled syringe to sit at room temperature for 30 minutes and the prefilled pen for 60 minutes prior to administering the injection. Warn patient not to warm syringe any other way. Have patient inspect the solution in the syringe before administering the injection. Solution should be clear and colorless to pale yellow. If solution is cloudy, discolored, or contains particles, instruct patient to discard it and use a new prefilled syringe. Also tell patient to discard the prefilled syringe or pen if not used within 14 days after being taken out of the refrigerator.
- Tell patient to inject the full amount in syringe to receive the prescribed dose.
- Instruct patient on infection precautions. Warn patient to avoid people with an active infection. Review signs and symptoms of an infection with patient and tell him to report any such evidence to prescriber immediately.
- Warn patient that allergic reactions can occur with sarilumab therapy. Tell patient to alert prescriber if present, as drug may have to be discontinued if reaction is serious.
- Inform patient that frequent blood tests will have to be performed to monitor for adverse effects. Stress importance of patient compliance with these appointments.
- Warn patient not to receive any live vaccines while taking sarilumab.
- Instruct patient to notify prescriber and seek immediate emergency medical attention if abdominal signs and symptoms such as pain occur.

**saxagliptin hydrochloride**

**Onglyza**

## Class and Category

*Pharmacologic class:* Dipeptidyl peptidase-4 (DPP-4) inhibitor

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *To improve blood glucose control in type 2 diabetes mellitus as adjunct to diet and exercise*

### **TABLETS**

**Adults.** 2.5 or 5 mg once daily

***DOSAGE ADJUSTMENT*** For patients with moderate or severe renal impairment (creatinine clearance 45 ml/min or less), patients with end-stage renal disease, patients having hemodialysis, and patients receiving strong CYP3A4/5 inhibitors (i.e., atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin), dosage shouldn't exceed 2.5 mg once daily.

Route	Onset	Peak	Duration
P.O.	Unknown	2 hr	24 hr

## Mechanism of Action

Incretin hormones, such as glucose-dependent insulintropic polypeptide (GIP) and glucagons-like peptide-1 (GLP-1), are released into bloodstream from small intestine in response to meals. Upon arrival at the pancreas, they stimulate pancreatic beta cells to release insulin. GLP-1 also reduces

glucagon secretion from pancreatic alpha cells, which reduces hepatic glucose production. Incretin hormones become inactivated within minutes of release by the enzyme, dipeptidyl peptidase-4. Saxagliptin inhibits this enzyme, thereby slowing inactivation of incretin hormones, which provides more time for them to increase insulin levels and blunt glucagon secretion. More insulin and less hepatic glucose production work together to lower blood glucose levels.

## Contraindications

Hypersensitivity to saxagliptin or its components

## Interactions

### DRUGS

*insulin, sulfonylureas*: Increased risk of hypoglycemia  
*strong CYP3A4/5 inhibitors such as atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin*: Increased plasma saxagliptin level  
*insulin, sulfonylureas*: Increased risk of hypoglycemia

## Adverse Reactions

**CNS**: Headache

**CV**: **Heart failure**, peripheral edema

**EENT**: Sinusitis, nasopharyngitis

**ENDO**: **Hypoglycemia**

**GI**: **Acute pancreatitis**, abdominal pain, gastroenteritis, vomiting

**GU**: Elevated plasma creatinine level, UTI

**HEME**: **Lymphopenia**

**MS:** Arthralgia (disabling, severe), **rhabdomyolysis**

**RESP:** Upper respiratory tract infection

**SKIN:** Bullous pemphigoid, **exfoliative skin conditions**, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that saxagliptin shouldn't be used to treat type 1 diabetes mellitus or diabetic ketoacidosis.
- Use cautiously in patients who have experienced angioedema with another dipeptidyl peptidase-4 inhibitor because it is not known if a cross-sensitivity reaction may occur with saxagliptin.
- Obtain a serum creatinine level, as ordered, before starting saxagliptin therapy and then periodically thereafter to monitor patient's renal function.
- Monitor patient closely for hypersensitivity to saxagliptin, especially within the first 3 months of therapy beginning with first dose. These reactions can be serious and life-threatening and may include anaphylaxis, angioedema, and exfoliative skin conditions. Discontinue saxagliptin immediately if hypersensitivity occurs, and notify prescriber.

- Monitor patient's blood glucose level and hemoglobin A<sub>1c</sub> to assess effectiveness of saxagliptin therapy.
- Monitor patient for signs and symptoms of heart failure during saxagliptin therapy because drug may increase risk. If present, notify prescriber, expect drug to be discontinued, and provide supportive care, as ordered.
- Watch for hypoglycemia in patients taking insulin or other antidiabetics, such as sulfonylureas. Expect dosage of insulin or other antidiabetics, such as sulfonylureas, to be decreased to reduce risk of hypoglycemia.
- Monitor patient for signs and symptoms of acute pancreatitis such as severe, sharp pain in the upper abdominal accompanied by fever, nausea, and vomiting. If present, notify prescriber, expect to stop saxagliptin, as ordered, and provide supportive care, as indicated and ordered.

## **PATIENT TEACHING**

- Emphasize that saxagliptin isn't a replacement for diet and exercise therapy.
- Explain importance of self-monitoring glucose levels during saxagliptin therapy.
- Teach patient to recognize hypoglycemia and how to treat it if it should occur. Urge him to carry glucose with him at all times in case hypoglycemia occurs.
- Review signs and symptoms of heart failure with patient, such as difficulty breathing; swelling of feet, hands, or legs; or unexplained weight gain. Tell patient to notify prescriber immediately, if present.
- Instruct patient to notify prescriber if fever, illness, infection, surgery, trauma, or other stress occurs because blood glucose control may be altered, requiring temporary insulin therapy.
- Tell patient to watch for the development of blisters or breakdown of the outer layer of his skin. If present, he should notify prescriber, as drug may need to be discontinued.
- Instruct patient to seek immediate medical attention if he experiences persistent, acute abdominal pain, fever, nausea, and vomiting, as well as any sign of hypersensitivity, such as difficulty breathing or swallowing, hives, rash, skin flaking or peeling, or swelling of any area on face or skin.
- Advise patient to seek medical attention if severe joint pain occurs. Tell patient that joint pain may develop within a day of taking saxagliptin or may develop years later.

# scopolamine transdermal system

**Transderm-Scop, Transderm-V (CAN)**

## Class and Category

*Pharmacologic class:* Belladonna alkaloid

*Therapeutic class:* Antiemetic

## Indications and Dosages

- *To prevent nausea and vomiting associated with motion sickness or recovery from anesthesia and/or opiate analgesia and surgery*

## TRANSDERMAL SYSTEM

**Adults and adolescents.** 1 U.S. transdermal system (1 mg) applied behind ear before antiemetic effect is required as follows: 4 hr before event known to cause motion sickness, evening before surgery, or 1 hr before caesarian section. Patch removed 24 hr postsurgical procedure. Patch may remain in place up to 3 days for prevention of motion sickness and may be replaced, as needed. Or, 1 Canadian transdermal system (1 mg) applied behind ear for 3-day period, beginning at least 12 hr before antiemetic effect is required.

***DOSAGE ADJUSTMENT*** Dosage reduction possible for elderly patients because of increased sensitivity to scopolamine.

## Mechanism of Action

Blocks neural pathways in the inner ear to relieve motion sickness.

## Contraindications

Angle-closure glaucoma; hypersensitivity to scopolamine, other belladonna alkaloids, or their components

Route	Onset	Peak	Duration
Transdermal	4 hr	Unknown	72 hr

## Interactions

### DRUGS

*anticholinergics (other)*: Possibly intensified anticholinergic effects including CNS adverse reactions, intestinal obstruction, and/or urinary retention

*CNS depressants*: Possibly potentiated effects of either drug, resulting in additive sedation

*oral drugs absorbed in stomach*: Possibly delayed absorption of oral drugs

### ACTIVITIES

*alcohol use*: Additive CNS effects

## Adverse Reactions

**CNS**: Agitation, amnesia, attention disturbance, confusion, coordination abnormalities, delusions, dizziness, drowsiness, euphoria, exacerbation of psychosis, hallucinations, headache, insomnia, memory loss,

paradoxical stimulation paranoia, restlessness, speech disorder, **seizures**, somnolence, vertigo

**CV:** Palpitations, tachycardia

**EENT:** Acute angle closure glaucoma; amblyopia; blurred vision; dry eyes, mouth, nose, and throat; eyelid irritation; increased intraocular pressure; itchy eyes; mydriasis; pharyngitis

**GI:** Constipation, decreased gastrointestinal motility, dysphagia

**GU:** Dysuria, urinary hesitancy, urine retention

**SKIN:** Decreased sweating, dry skin, erythema, flushing, rash, skin irritation

**Other:** Application site burning, withdrawal symptoms upon removal of patch

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug should be avoided in pregnant women experiencing severe preeclampsia because of increased risk for eclamptic seizures.
- Use with caution only if benefit to mother outweighs potential risk to fetus in other circumstances.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Assess for bladder distention and monitor urine output because drug's antimuscarinic effects can cause urine retention. Also, monitor bowel

sounds as drug may decrease gastrointestinal motility. Know that patch should be removed in patients experiencing difficulty in urination.

- Monitor patient who has worn the patch for several days for withdrawal symptoms, which usually occur 24 hours or more after the patch has been removed.
- Monitor for pain. In presence of pain, drug may act as a stimulant and produce delirium if used without meperidine or morphine.
- Monitor heart rate for transient tachycardia, which may occur with high doses of drug. Rate should return to normal within 30 minutes.
- Monitor patient for visual adverse effects; nervous system adverse reactions including cognitive, psychiatric reactions, and seizures; decreased gastrointestinal motility; urinary retention; and withdrawal symptoms.
- Remove patch before patient undergoes an MRI as skin burns may occur if left in place.

## **PATIENT TEACHING**

- Instruct patient to apply scopolamine transdermal patch on hairless area behind ear and to wash hands thoroughly with soap and water before and after applying. Remind patient that only one transdermal patch should be worn at one time. Patch should not be cut. If patch becomes displaced, tell patient to remove it and apply a new one. When removing the old patch, instruct patient to fold the used patch in half with the sticky side together and discard in a manner that prevents accidental contact or ingestion by children or pets.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to avoid alcohol while wearing the scopolamine patch.
- If patient complains of dry eyes, suggest lubricating drops.
- Advise patient to immediately remove the transdermal system and contact prescriber if experiencing blurred vision, eye pain or discomfort, or halos or colored images in association with red eyes from conjunctival congestion and corneal edema.
- Review adverse reactions associated with drug and advise patient to alert prescriber if prolonged, severe, or unusual. Tell patient wearing patch for more than a couple of days to be alert for signs of withdrawal when patch is removed. If severe, patient should contact prescriber.

- Instruct patient to remove patch if undergoing a MRI as skin burns can occur if left in place.

## secobarbital sodium

**Novosecobarb (CAN), Seconal**

### Class, Category, and Schedule

*Pharmacologic class:* Barbiturate

*Therapeutic class:* Sedative-hypnotic

*Controlled substance schedule:* II

### Indications and Dosages

➤ *To induce sedation before surgery*

#### CAPSULES

**Adults.** 200 to 300 mg 1 to 2 hr before surgery.

**Children.** 2 to 6 mg/kg 1 to 2 hr before surgery.

*Maximum:* 100 mg.

➤ *To provide short-term treatment of insomnia*

#### CAPSULES

**Adults.** 100 mg at bedtime.

***DOSAGE ADJUSTMENT*** Reduced dosage required for debilitated or elderly patients and those with hepatic or renal dysfunction.

---

**Route**

**Onset**

**Peak**

**Duration**

Route	Onset	Peak	Duration
P.O.	10-15 min	15-30 min	1-4 hr

## Mechanism of Action

Inhibits upward conduction of nerve impulses to the reticular formation of the brain, thereby disrupting impulse transmission to the cortex. This action depresses the CNS, producing drowsiness, hypnosis, and sedation.

## Contraindications

History of manifest or latent porphyria; hypersensitivity to secobarbital, other barbiturates, or their components; severe hepatic or respiratory impairment in which dyspnea or obstruction is evident

## Interactions

### DRUGS

*CNS depressants:* Additive depressant effects

*corticosteroids, oral anticoagulants:* Decreased plasma levels of these drugs with decreased effectiveness

*doxycycline:* Shortened half-life by secobarbital for as long as 2 weeks after barbiturate therapy is discontinued

*estradiol, estrone, progesterone, and other steroidal*

*hormones:* Decreased effectiveness of these drugs

*griseofulvin:* Interference with absorption of oral griseofulvin

*MAO inhibitors:* Prolonged effect of secobarbital increasing risk of adverse reactions

*phenytoin:* Effects on metabolism of phenytoin variable requiring close monitoring

*sodium valproate, valproic acid*: Increased secobarbital serum levels

## ACTIVITIES

*alcohol use*: Increased CNS depression

## Adverse Reactions

**CNS**: Anxiety, clumsiness, confusion, depression, dizziness, drowsiness, hangover, headache, insomnia, irritability, lethargy, nervousness, nightmares, paradoxical stimulation, syncope

**CV**: Hypotension

**EENT**: Laryngospasm

**GI**: Anorexia, constipation, nausea, vomiting

**MS**: Arthralgia, muscle weakness

**RESP**: Apnea, bronchospasm, respiratory depression

**SKIN**: Jaundice

**Other**: Drug dependence, weight loss

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm as drug crosses placental barrier and may cause fetal abnormalities. It also may cause Neonatal Acute Withdrawal Syndrome if mother received drug during last trimester of pregnancy. The syndrome may cause hyperirritability and seizures from birth to a delayed onset of up to 14 days.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Full anesthetic doses of drug decreases the force and frequency of uterine contractions.
- It may also cause respiratory depression in the neonate, especially if infant is premature at time of birth. If drug is used during labor and delivery, resuscitation equipment should be available.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that prolonged use of secobarbital may lead to tolerance and physical and psychological dependence.

**WARNING** To avoid withdrawal symptoms, expect to taper drug after long-term therapy. Withdrawal symptoms usually appear 8 to 12 hours after stopping drug and may include anxiety, insomnia, muscle twitching, nausea, orthostatic hypotension, vomiting, weakness, and weight loss. Severe symptoms may include delirium, hallucinations, and seizures. Generalized tonic-clonic seizures may occur within 16 hours or up to 5 days after last dose.

- Assess patient for signs and symptoms of barbiturate toxicity, including dyspnea, severe confusion, and severe drowsiness. Notify prescriber immediately if they appear because barbiturate toxicity may be life-threatening.
- Expect prescriber to provide patient with the least possible quantity of secobarbital to minimize the risk of acute or chronic overdose. For patients who are depressed, drug-dependent, or suicidal or who have a history of drug abuse, institute precautions to prevent drug hoarding and overdose.

## PATIENT TEACHING

- Instruct patient to take secobarbital exactly as prescribed because of the risk of addiction.
- Inform patient that taking drug with food may reduce adverse GI effects.
- Advise patient to avoid alcohol and caffeine and potentially hazardous activities during therapy.
- Inform patient about possible hangover effect.
- Recommend to patient taking an oral contraceptive to use an additional form of birth control during therapy.
- Caution patient not to stop taking drug abruptly.
- Instruct patient to notify prescriber of bone pain, muscle weakness, or unexplained weight loss during therapy.

**selegiline hydrochloride**

**Zelapar**

**selegiline transdermal  
system**

**Emsam**

## Class and Category

*Pharmacologic class:* Monoamine oxidase inhibitor (MAOI)

*Therapeutic class:* Antidepressant (Emsam), antidyskinetic

## Indications and Dosages

- *As adjunct to carbidopa-levodopa therapy to treat Parkinson's disease*

## **CAPSULES, TABLETS**

**Adults.** 5 mg twice daily with breakfast and lunch.

- *As adjunct to carbidopa-levodopa therapy to treat Parkinson's disease in patients whose response to therapy has deteriorated*

## **ORALLY DISINTEGRATING TABLETS (ZELAPAR)**

**Adults. Initial:** 1.25 mg once daily before breakfast for at least 6 wk; then increased to 2.5 mg once daily, as needed.

***DOSAGE ADJUSTMENT*** For patients with mild-to-moderate hepatic dysfunction, dosage kept at 1.25 mg once daily.

- *To treat depression*

## **TRANSDERMAL SYSTEM (EMSAM)**

**Adults. Initial:** 6 mg/24 hr with patch applied daily to upper torso, upper thigh, or outer surface of upper arm. Increased every 2 wk in increments of 3 mg/24 hr, as needed.

**Maximum:** 12 mg/24 hr.

## **Mechanism of Action**

Reduces dopamine metabolism by noncompetitively inhibiting the brain enzyme monoamine oxidase type B. This increases the amount of dopamine available to relieve symptoms of Parkinsonism. Selegiline's metabolites may also enhance dopamine transmission by inhibiting its reuptake at synapses.

# Contraindications

*For all forms:* Hypersensitivity to selegiline or its components; *For oral forms:* Concurrent therapy with meperidone and other opioids; *For transdermal form:* Children less than 12 years, concomitant therapy within 2 weeks with carbamazepine, dextromethorphan, dual serotonin and norepinephrine reuptake inhibitors (duloxetine, venlafaxine), opiate analgesics (meperidine, methadone, pentazocine, propoxyphene, tramadol), oxcarbazepine, selective serotonin reuptake inhibitors (fluoxetine [use within 5 weeks], paroxetine, sertraline), tricyclic antidepressants (clomipramine, imipramine); pheochromocytoma

# Interactions

## DRUGS

*amphetamines, buspirone, sympathomimetic amines:* Increased risk of severe hypertension  
*carbamazepine:* Increased risk of hypertensive crisis  
*serotonergic drugs such as dextromethorphan, opiate analgesics (meperidine, tramadol, methadone, pentazocine, propoxyphene), selective serotonin reuptake inhibitors (fluoxetine, sertraline, paroxetine), serotonin and norepinephrine reuptake inhibitors (duloxetine, venlafaxine), tricyclic antidepressants (clomipramine, imipramine:* Increased risk of serotonin syndrome

## FOODS

*foods that contain tyramine or other high-pressor amines:* Increased risk of sudden and severe hypertension

## ACTIVITIES

*alcohol use such as tap beer and beers not pasteurized:*  
Increased risk of hypertension

## Adverse Reactions

**CNS:** Anxiety, chills, compulsive behaviors such as intense urges to perform certain activities (such as gambling or sex), confusion, dizziness, drowsiness, dyskinesia, euphoria, extrapyramidal reactions, falling asleep during activities of daily living, fatigue, hallucinations, headache, insomnia, irritability, lethargy, memory loss, mood changes, nervousness, paresthesia, precipitation of manic/mixed episodes, restlessness, **serotonin syndrome**, **suicidal ideation**, syncope, tremor, weakness

**CV:** **Arrhythmias**, chest pain, hypertension, orthostatic hypotension, palpitations, peripheral edema

**EENT:** Altered taste, blepharospasm, blurred vision, burning lips or mouth, diplopia, dry mouth, pharyngitis, sinusitis, tinnitus

**GI:** Abdominal pain, anorexia, constipation, diarrhea, **GI bleeding**, heartburn, nausea, vomiting

**GU:** Dysuria, urinary hesitancy, urinary urgency, urine retention

**MS:** Arthralgia, back and leg pain, muscle fatigue and spasms, neck stiffness

**RESP:** **Asthma**

**SKIN:** Diaphoresis, photosensitivity, rash

**Other:** Application site reactions (Emsam)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding if using oral form.
- Breastfeeding not recommended during treatment with transdermal form and for 5 days after the final dose.

## Nursing Considerations

- Expect to screen patient for a family or personal history of bipolar disorder, hypomania, or mania before selegiline therapy is begun, because drug may precipitate manic/mixed episodes.
- Assess patient for mental status and mood changes because selegiline can worsen such conditions as dementia, severe psychosis, tardive dyskinesia, and tremor. Be especially alert for suicidal tendencies, particularly when therapy starts or dosage changes.
- Monitor patient who is also taking levodopa for levodopa-induced adverse reactions, including confusion, dyskinesia, hallucinations, nausea, and orthostatic hypotension.
- Monitor for decreased symptoms of Parkinson's disease to evaluate drug's effectiveness.

**WARNING** Monitor patient for serotonin syndrome, which can be life-threatening. Signs and symptoms to watch for include autonomic instability, gastrointestinal symptoms, mental status changes, neuromuscular changes, and seizures. If present stop selegiline therapy immediately (remove transdermal system, if present), notify prescriber, and provide supportive care, as ordered.

- Be aware that drug can reactivate gastric ulcers because it prevents breakdown of gastric histamine. Assess for related signs and symptoms, such as abdominal pain.
- Assess patient for skin changes regularly because risk of melanoma is increased in patients with Parkinson's disease. It isn't clear whether increase results from disease or drugs used to treat it.

## **PATIENT TEACHING**

- Caution patient to take only prescribed amount because increased dosage may cause severe adverse reactions.
- Advise patient to avoid taking selegiline in the late afternoon or evening because it may interfere with sleep.
- For orally disintegrating tablets, tell patient to take it before breakfast without any liquid. Caution him not to push tablet through the foil on the blister pack but instead to peel back the foil with dry hands and gently remove the tablet. He should then immediately place the tablet on top of his tongue and let it disintegrate. Advise him not to drink or ingest any food for 5 minutes before and after taking the drug.
- Instruct patient taking tablet form to store blister tablets in sachet pouch at all times and to keep pouch inside a clear child-resistant pouch provided. Unused tablets should be discarded after 3 months of opening pouch. Store pouch at room temperature.
- For transdermal form, explain how and where (outer surface of upper arm, upper torso below the neck and above the waist, or upper thigh) to apply patch, stressing need to rotate sites. Remind patient to apply patch at about the same time of day. Tell patient not to apply patch to broken, calloused, hairy, irritated, oily, or scarred skin. Also, patch should not be placed where clothing is tight. Have patient wash the area gently and thoroughly with soap and warm water, then rinse until all soap is removed. After drying area, patch is ready to be applied. Tell patient to wash hands well after application and to dispose of removed patch immediately.
- Emphasize that only one patch may be worn at a time. If a patch falls off, tell patient to apply a new patch to a new site and to resume previous schedule.
- Caution patient to avoid exposing transdermal patch to sources of direct heat, such as electric blankets, heat lamps, heating pads, hot tubs, prolonged sunlight exposure or saunas.
- Tell patient not to cut transdermal patch into smaller pieces.

- Urge caregiver to monitor patient closely for suicidal tendencies, especially when therapy starts or dosage changes.

**WARNING** Urge patient to avoid tyramine-rich foods and beverages during and for 2 weeks after stopping selegiline therapy unless patient is prescribed the lowest dosage of transdermal system (6 mg/24 hours), which doesn't require diet modification. Review which foods are considered tyramine-rich. Stress importance of seeking immediate medical attention if the following acute symptoms occur: heart racing or palpitations, neck stiffness, severe headache, or other sudden or unusual symptoms.

- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to immediately report neck stiffness, palpitations, racing heart, severe headache, or other sudden or unusual symptoms.
- Advise patient to change positions slowly to minimize the effects of orthostatic hypotension.
- Suggest that patient elevate his legs when sitting to reduce ankle swelling.
- Urge patient to avoid excessive sun exposure.
- Instruct patient to notify prescriber if symptoms develop that could indicate overdose, including muscle twitching and eye spasms.
- Urge patient to notify prescriber if dry mouth lasts longer than 2 weeks. Advise him to have routine dental checkups.
- Urge patient to have regular skin examinations done by a dermatologist or other qualified health professional.
- Tell patient to inform prescriber of any new medications, including prescription drugs, over-the-counter drugs, and including herbal preparations.
- Advise patient to notify prescriber about intense urges (as for gambling or sex) because dosage may have to be reduced or drug discontinued.
- Inform mothers wishing to breastfeed their infants that breastfeeding is not recommended during treatment with selegiline and for 5 days after

final dose.

# semaglutide

## Ozempic

### Class and Category

*Pharmacologic class:* Glucagon-like peptide-1 (GLP-1) receptor agonist

*Therapeutic class:* Antidiabetic

### Indications and Dosages

- *As adjunct to diet and exercise to improve glycemic control in type 2 diabetes mellitus; to reduce risk of major adverse cardiovascular events (cardiovascular death, nonfatal MI or stroke) in patients with type 2 diabetes mellitus and established cardiovascular disease*

### SUBCUTANEOUS INJECTION

**Adults.** *Initial:* 0.25 mg once a wk for 4 wk, then increased to 0.5 mg once a wk. Dosage further increased to 1 mg once a wk, if needed, after another 4 wk. *Maximum:* 1 mg once a wk.

### Mechanism of Action

Selectively binds to and activates the GLP-1 receptor to reduce blood glucose through a mechanism that stimulates

insulin secretion and lowers glucagon secretion, both in a glucose-dependent manner. Thus, when blood glucose is high, insulin secretion is stimulated and glucagon secretion is inhibited, to lower blood glucose levels. A minor delay in gastric emptying in the early postprandial phase may also cause a minor glucose lowering action.

## Contraindications

Family or personal history of medullary thyroid carcinoma, hypersensitivity to semaglutide or its components, multiple endocrine neoplasia syndrome type 2 (MEN 2)

## Interactions

### DRUGS

*insulin, insulin secretagogues such as sulfonylureas:*

Increased risk of hypoglycemia

*oral drugs:* Delayed absorption of these drugs

## Adverse Reactions

**CNS:** Dizziness, fatigue

**EENT:** Distortion of taste

**ENDO:** **Hypoglycemia**

**GI:** Abdominal pain, cholelithiasis, constipation, diarrhea, dyspepsia, elevated pancreatic enzymes, flatulence, gastroesophageal reflux disease, gastritis, nausea, **pancreatitis**, vomiting

**GU:** **Acute kidney injury, worsening of chronic renal failure**

**Other:** Anti-semaglutide antibodies, injection-site reactions (discomfort, erythema)

# Childbearing Considerations

## PREGNANCY

- Drug may cause fetal harm based on animal studies.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## REPRODUCTION

- Women of childbearing age should be advised to consult prescriber for an alternative drug to treat diabetes at least 2 months before a planned pregnancy.

# Nursing Considerations

- Be aware that semaglutide is not recommended as a first-line therapy for patients who have inadequate glycemic control using diet and exercise, because of the uncertain relevance of possible tumor findings in animals.
- Know that semaglutide should not be given to patients with a history of pancreatitis, because effects are unknown. Monitor all patients for signs and symptoms of pancreatitis such as persistent severe abdominal pain which sometimes may radiate to the back and which may or may not be accompanied by vomiting. If pancreatitis is suspected, expect drug to be discontinued.
- Monitor patient with a history of diabetic retinopathy for progression of the disorder.
- Monitor patient for hypoglycemia, especially if patient is also taking insulin or an insulin secretagogue such as a sulfonylurea.
- Monitor patient closely for renal dysfunction, especially when initiating or escalating the dose of semaglutide or if patient develops severe adverse

gastrointestinal reactions.

**WARNING** Know that other drugs in the same class as semaglutide have caused serious hypersensitivity reactions such as anaphylaxis and angioedema. Monitor patient for such reactions. If present, stop drug therapy immediately and provide supportive care, as needed and prescribed.

## **PATIENT TEACHING**

- Teach patient or caregiver how to administer a subcutaneous injection. Tell her to administer drug into the abdomen, thigh, or upper arm using a different injection site each time.
- Instruct patient to administer the once-weekly dosage at the same day each week at any time of the day and without regard to meals. However, let patient know that the day of weekly administration can be changed, if needed, as long as the time between two doses is more than 48 hours.
- Inform patient that if a dose is missed, she should take the drug as soon as possible if within 5 days after the missed dose. If more than 5 days have passed, she should skip the missed dose and administer the next dose on the regularly scheduled day.
- Tell patient who is also administering insulin to administer the two drugs as separate injections and never to mix them. The two injections can be administered in the same body region, but injections should not be adjacent to each other.
- Remind patient never to share the semaglutide pen with anyone else, even if the needle has been changed, because of an increased risk of transmitting bloodborne pathogens.
- Review signs and symptoms of hypoglycemia with patient and how to treat if it should occur. This is especially important in patients at increased risk, such as patients taking concurrent insulin or a sulfonylurea.
- Tell patient to report acute gastrointestinal adverse reactions, severe abdominal pain that may or may not radiate to the back and possibly be accompanied by vomiting. Tell patient to report any visual changes to prescriber.
- Advise women of childbearing age to alert prescriber if pregnancy occurs.

**WARNING** Warn patient to seek immediate emergency care if severe or persistent signs and symptoms of an allergic reaction occur.

# sertraline hydrochloride

**Zoloft**

## Class and Category

*Pharmacologic class:* Selective serotonin reuptake inhibitor (SSRI)

*Therapeutic class:* Antianxiety, antidepressant, antiobsessant, antipanic, antiposttraumatic stress, antipremenstrual dysphoric

## Indications and Dosages

➤ *To treat major depression*

### ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 50 mg daily, increased in increments of 25 to 50 mg daily every wk, as needed. *Maximum:* 200 mg daily.

➤ *To treat obsessive-compulsive disorder*

### ORAL SOLUTION, TABLETS

**Adults and adolescents.** *Initial:* 50 mg daily, increased in increments of 25 to 50 mg daily every wk, as needed. *Maximum:* 200 mg daily.

**Children ages 6 to 12.** *Initial:* 25 mg daily, increased in increments of 25 mg every wk, as needed. *Maximum:* 200 mg daily.

- *To treat panic disorder, with or without agoraphobia; to treat posttraumatic stress disorder; to treat social anxiety disorder*

## ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 25 mg daily, increased by 25 to 50 mg daily every wk, as needed.

*Maximum:* 200 mg daily.

- *To treat premenstrual dysphoric disorder (PMDD)*

## ORAL SOLUTION, CONCENTRATE, TABLETS

**Adult women.** *Initial:* 50 mg daily in morning or evening throughout menstrual cycle; or, 50 mg daily in morning or evening during luteal phase of menstrual cycle only. (starting 14 days prior to menses and continuing through onset of menses). Dosage increased each menstrual cycle in 50-mg increments up to 150 mg daily, or each luteal phase up to 100 mg daily, as needed. If 100-mg daily dosage given, dosage regimen given as 50 mg daily for first 3 days followed by 100 mg daily during remaining dosage cycle.

*Maximum:* 150 mg daily for dosing throughout menstrual cycle, or 100 mg daily for dosing during luteal phase only.

**DOSAGE ADJUSTMENT** For patients with mild hepatic dysfunction, all dosages reduced by 50%.

Route	Onset	Peak	Duration
P.O.	2-4 wk*	Unknown	Unknown

\* For antidepressant and antipanic effects.

## Mechanism of Action

Inhibits reuptake of the neurotransmitter serotonin by CNS neurons, thereby increasing the amount of serotonin available in nerve synapses. An elevated serotonin level may result in elevated mood and reduced depression. This action may also relieve symptoms of other psychiatric conditions attributed to serotonin deficiency and premenstrual dysphoric disorder.

## Contraindications

Concurrent use of disulfiram (oral solution) or pimozide; hypersensitivity to sertraline or its components; use within 14 days of an MAO inhibitor, including intravenous methylene blue and linezolid.

## Interactions

### DRUGS

*antibiotics (erythromycin, gatifloxacin, moxifloxacin, sparfloxacin), antipsychotics (chlorpromazine, droperidol, iloperidone, mesoridazine, ziprasidone), Class 1A*

*antiarrhythmics (procainamide, quinidine), Class III*

*antiarrhythmics (amiodarone, sotalol), dolasetron, halofantrine, levomethadyl, mefloquine, methadone, pentamidine, pimozide, probucol, tacrolimus: Increased risk of QT-interval prolongation and/or ventricular arrhythmias*

*aspirin, clopidogrel, heparin, NSAIDs, warfarin: Increased anticoagulant activity and risk of bleeding*

*atomoxetine, desipramine, dextromethorphan, flecainide, metoprolol, nebivolol, perphenazine, phenytoin, propafenone, thioridazine, tolterodine, venlafaxine: Possibly*

increased blood levels of these drugs, leading to increased risk of arrhythmias

*buspirone, fentanyl, lithium, MAO inhibitors (I.V. methylene blue, linezolid, selegiline, tranylcypromine), other selected serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, St. John's wort, tricyclic*

*antidepressants, triptans, tryptophan:* Increased risk of potentially fatal serotonin syndrome

*highly bound drugs to plasma protein:* Increased free concentrations of sertraline, increasing risk of adverse reactions

## Adverse Reactions

**CNS:** Abnormal dreams, aggressiveness, agitation, amnesia, anxiety, apathy, ataxia, **cerebrovascular spasm**, **coma**, confusion, delusions, depression, dizziness, drowsiness, emotional lability, euphoria, extrapyramidal symptoms, fatigue, fever, hallucination, headache, hyperkinesia, hypoesthesia, insomnia, lethargy, malaise, nervousness, **neuroleptic malignant syndrome-like reaction**, paranoid reaction, paresthesia, psychomotor hyperactivity, psychosis, **seizures**, **serotonin syndrome**, somnolence, **suicidal ideation**, syncope, tremor, weakness, yawning

**CV:** **Atrial arrhythmias**, **AV block**, **bradycardia**, hypertension, palpitations, **prolonged QT interval**, **torsades de pointes**, vasculitis, vasodilation, **ventricular tachycardia**

**EENT:** Abnormal accommodation, acute closure glaucoma, blindness, cataract, conjunctivitis, dry mouth, earache, epistaxis, eye pain, optic neuritis, rhinitis, sinusitis, teeth grinding, tinnitus, vision changes

**ENDO:** Galactorrhea, hyperglycemia, hyperprolactinemia, hypothyroidism, syndrome of inappropriate ADH secretion

**GI:** Abdominal cramps or pain, anorexia, constipation, diarrhea, elevated liver enzymes, flatulence, hepatic dysfunction, **hepatic failure**, **hepatitis**, increased appetite, indigestion, jaundice, nausea, **pancreatitis**, vomiting

**GU:** **Acute renal failure**; anorgasmia; decreased libido; ejaculation disorders; enuresis; hematuria; impotence; leucorrhea; menstrual disorders; priapism; polyuria; urinary frequency, incontinence, or retention; vaginal hemorrhage

**HEME:** **Agranulocytosis**, **altered platelet function**, **aplastic anemia**, **hemorrhage**, **leukopenia**, **pancytopenia**, **thrombocytopenia**

**MS:** Arthralgia, dystonia, lockjaw, muscle cramps or weakness, myalgia, **rhabdomyolysis**

**RESP:** **Bronchospasm**, coughing, dyspnea, **pulmonary hypertension**

**SKIN:** Alopecia, dermatitis including bullous, diaphoresis, flushing, photosensitivity, pruritus, purpura, rash, severe cutaneous disorders, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **hyponatremia**, lupus-like syndrome, serum sickness, weight loss

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm, especially if given in late pregnancy, as drug exposure increases risk of multiple neonatal complications after birth including feeding difficulties, respiratory complications, seizures, and persistent pulmonary hypertension of the newborn.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

- Oral solution contains 12% alcohol and is not recommended during pregnancy.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that sertraline should not be given to patients with bradycardia, congenital long QT syndrome, hypokalemia or hypomagnesemia, recent acute myocardial infarction, or uncompensated heart failure because of increased risk of prolonged QT interval and torsades de pointes. It should also not be given to patients who are taking other drugs that prolong the QT interval. Expect hypokalemia and hypomagnesemia to be corrected before sertraline therapy is begun.
- Monitor liver enzymes and BUN and serum creatinine levels, as appropriate, in patients with hepatic or renal dysfunction.

**WARNING** Monitor patient closely for evidence of serotonin syndrome, such as agitation, coma, diarrhea, hallucinations, hyperthermia, hyperreflexia, incoordination, labile blood pressure, nausea, tachycardia, and vomiting. Serotonin syndrome in its most severe form can resemble neuroleptic malignant syndrome, which includes autonomic instability, hyperthermia, mental status changes, muscle rigidity, and possibly rapid changes in vital signs. Notify prescriber immediately because serotonin syndrome reactions that resemble neuroleptic malignant syndrome may be life-threatening. Be prepared to provide supportive care.

- Monitor patient for hypo-osmolality of serum and urine and for hyponatremia, which may indicate sertraline-induced syndrome of inappropriate ADH secretion.

- Be aware that effective antidepressant therapy can promote development of mania in predisposed people. If mania develops, notify prescriber immediately and expect to withhold sertraline.
- Watch closely for suicidal tendencies, especially when therapy starts and dosage changes and especially in children and adolescents.
- Monitor patient closely for evidence of GI bleeding, especially if patient takes a drug known to cause it, such as aspirin, an NSAID, or warfarin.
- When therapy stops, expect to taper dosage to minimize adverse effects rather than stopping drug abruptly.

## PATIENT TEACHING

- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute closure glaucoma. Encourage patient to have an eye exam before starting therapy to see if he is at risk.
- Inform patient that oral solution contains alcohol and should not be taken with disulfiram.
- Teach patient to dilute oral solution before taking it. Tell him to use supplied dropper to remove prescribed amount and mix it with 4 oz (one-half cup) of ginger ale, lemon or lime soda, lemonade, orange juice, or water. Warn him not to mix oral solution with anything else. Explain that it's normal for mixture to be slightly hazy.
- Tell patient to take dose immediately after mixing it.
- Advise patient with a latex sensitivity to use an alternate dispenser because the supplied dropper dispenser contains dry natural rubber.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Inform patient that use of certain drugs, such as aspirin, NSAIDs, other antiplatelet drugs, warfarin, or other anticoagulants, with sertraline may increase his risk for bleeding.

**WARNING** Tell patient that sertraline increases the risk of serotonin syndrome and reactions that resemble neuroleptic malignant syndrome, rare but serious complications, when taken with some other drugs. Teach patient how to recognize signs and symptoms of

these disorders and advise him to notify prescriber immediately if they occur.

- Warn family or caregiver to watch patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes, and especially if patient is a child or adolescent.
- Caution patient not to stop taking drug abruptly. Explain that gradual tapering helps to avoid withdrawal symptoms.
- Instruct female patients to notify prescriber if they are or could be pregnant.
- Advise patient to consult prescriber before taking any OTC product, especially aspirin products or NSAIDs.
- Alert patient that false-positive urine testing for benzodiazepines may occur while taking sertraline, requiring a more sensitive test to be performed.

## sevelamer hydrochloride

**Renagel**

## sevelamer carbonate

**Renvela**

### **Class and Category**

*Pharmacologic class:* Polymeric phosphate binder

*Therapeutic class:* Phosphate binder

### **Indications and Dosages**

- *To control serum phosphate level in patients with chronic kidney disease on dialysis*

## **TABLETS (RENAGEL)**

**Adults not taking a phosphate binder.** 800 mg three times a day with meals if serum phosphorus level is 5.5 to 7.5 mg/dl; or 1,600 mg three times a day with meals if serum phosphorus level is 7.5 mg/dl or greater.

**Adults switching from calcium acetate.** Dosage adjusted based on the serum phosphorous concentration and increased or decreased by 800 mg/meal at two-week intervals, as needed. If serum phosphorus level is greater than 5.5 mg/dl, dosage increased by 800 mg/meal at 2-week intervals; if serum phosphorus level is between 3.5 and 5.5 mg/dl dosage remains unchanged; and if serum phosphorus level is less than 3.5 mg/dl, dosage decreased by 800 mg/meal at 2-week intervals. *Maximum:* 13 g daily.

## **POWDER FOR ORAL SUSPENSION (RENVELA), TABLETS (RENVELA)**

**Adults not taking a phosphate binder.** 800 mg three times a day with meals if serum phosphorus level is 5.5 to 7.5 mg/dl; 1,600 mg three times a day with meals if serum phosphorus level is 7.5 mg/dl or greater. Dosage increased or decreased by 800 mg/meal at 2-wk intervals, as needed. *Maximum:* 14 g daily.

**Children age 6 years and over not taking a phosphate binder.** 800 mg three times a day with meals if serum phosphorus level is 0.75 mg/dl to less than 1.2 mg/dl, with dosage titrated every 2 weeks by 400 mg/meal, as needed; 1,600 mg three times a day with meals if serum phosphorus level is 1.2 mg/dl or greater, with dosage titrated every 2 weeks by 800 mg/meal, as needed.

**DOSAGE ADJUSTMENT** For adult patients being switched from calcium acetate to sevelamer carbonate, 800 mg of sevelamer can be substituted for every 667 mg of calcium being taken.

## Mechanism of Action

Inhibits phosphate absorption in the intestine by binding dietary phosphate, thereby lowering serum phosphorus level.

## Contraindications

Bowel obstruction; hypersensitivity to sevelamer carbonate, sevelamer hydrochloride, or their components

## Interactions

### DRUGS

*oral drugs such as ciprofloxacin, cyclosporine, levothyroxine, mycophenolate mofetil, tacrolimus:* Possible decreased bioavailability of oral drugs requiring separate administration times

## Adverse Reactions

**CNS:** Headache, fever

**CV:** Hypertension, **hypotension**, **thrombosis**

**EENT:** Nasopharyngitis

**GI:** Abdominal pain, constipation (severe), diarrhea, dysphagia, fecal impaction, flatulence, ileus, indigestion, **intestinal obstruction or perforation**, nausea, vomiting

**RESP:** Bronchitis, dyspnea, increased cough, upper respiratory tract infection

**MS:** Arthralgia, back or limb pain

**SKIN:** Pruritus, rash

**Other:** **Hypersensitivity reactions**, infection

## Childbearing Considerations

### PREGNANCY

- Drug is not absorbed systemically and is not expected to result in fetal exposure.
- Drug may decrease serum levels of fat-soluble vitamins and folic acid in pregnant women.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is not absorbed systemically.
- Drug is not expected to be in breast milk.

## Nursing Considerations

- Give other drugs at least 1 hour before or 3 hours after sevelamer to prevent interaction.
- Suggest suspension form be used in patients with swallowing disorders because tablet may get stuck in the esophagus in these individuals, and they may require hospitalization and emergency intervention to remove it.
- Be aware that severe hypophosphatemia may occur in patient with dysphagia, major GI tract surgery, or severe GI motility disorder (including severe constipation) because drug prevents phosphate absorption.
- Monitor blood pressure frequently.
- Monitor serum phosphorus level to determine drug's effectiveness; monitor other serum electrolyte levels, especially bicarbonate and chloride, to detect imbalances.

## PATIENT TEACHING

- Tell patient to take drug with meals and to swallow tablets whole with water and not to break, chew, crush, or open them.
- Instruct patient taking suspension form to mix entire contents of each packet of powder thoroughly with the amount of water indicated on packet. More than one packet can be mixed together. He should stir the mixture vigorously, even though it does not dissolve, and drink entire preparation immediately or up to 30 minutes later (but he will need to stir the mixture again vigorously right before drinking if it was not consumed immediately).
- Caution patient to take other drugs 1 hour before or 3 hours after sevelamer.
- Review symptoms of thrombosis, and advise patient to report them immediately.
- Instruct patient to report new onset or worsening of existing constipation to prescriber because additional treatment may be needed to prevent serious complications.
- Inform patient of potential need for fat-soluble vitamins and folic acid supplements, especially if patient is pregnant.

## sildenafil citrate

### Revatio, Viagra

## Class and Category

*Pharmacologic class:* Phosphodiesterase 5 (PDE5) inhibitor

*Therapeutic class:* Antihypertensive (pulmonary arterial),  
erectile dysfunction agent

## Indications and Dosages

- *To treat erectile dysfunction*

## **TABLETS (VIAGRA)**

**Men.** *Initial:* 50 mg taken 30 min to 4 hr before sexual activity although best if taken 1 hr before sexual activity; decreased or increased as needed based upon response. *Usual range:* 25 to 100 mg daily. *Maximum:* Once per day with dosage not exceeding 100 mg.

***DOSAGE ADJUSTMENT*** Initially, 25 mg for men over 65 years of age, those with hepatic dysfunction or severe renal insufficiency (creatinine clearance less than 30 ml/min) and those taking an alpha blocker or potent CYP3A4 inhibitors (erythromycin, itraconazole, ketoconazole, saquinavir), or ritonavir. Maximum dosage for patient taking ritonavir is 25 mg within a 48 hr period.

- *To treat pulmonary arterial hypertension in order to improve exercise ability and delay clinical worsening of condition in patients classified as group 1 by the World Health Organization*

## **ORAL SUSPENSION, TABLETS (REVATIO)**

**Adults.** 5 or 20 mg three times a day 4 to 6 hr apart.

## **I.V. INJECTION (REVATIO)**

**Adults.** 2.5 or 10 mg administered as bolus three times a day.

Route	Onset	Peak	Duration
P.O.	In 30 min	Unknown	4 hr

## **Mechanism of Action**

Enhances the effect of nitric oxide released in the penis by stimulation. Nitric oxide increases cGMP level, relaxes smooth muscle, and increases blood flow to the corpus cavernosum, thus producing an erection.

By preventing breakdown of cyclic guanosine monophosphate by phosphodiesterase, levels increase leading to smooth muscle relaxation of the pulmonary vasculature and subsequently, vasodilation. Vasodilation causes the pressure within the pulmonary vasculature to decrease, which improves tolerance to exercise and delays worsening of pulmonary arterial hypertension.

## Contraindications

Concomitant riociguat, a guanylate cyclase stimulator, continuous or intermittent nitrate therapy, hypersensitivity to sildenafil or its components

## Interactions

### DRUGS

*alpha-blockers, amlodipine, nitrates:* Possible additive blood pressure-lowering effects

*erythromycin, itraconazole, ketoconazole, ritonavir, saquinavir, and other CYP3A4 inhibitors:* Significantly increased systemic exposure of sildenafil, increasing risk of adverse reactions

## Adverse Reactions

**CNS:** **CVA**, dizziness, headache, migraine, **seizures**, syncope, transient global amnesia, transient ischemic attack

**CV:** Heart failure, hypertension, hypotension, myocardial infarction or ischemia, orthostatic hypotension, palpitations, sudden cardiac death, tachycardia, vaso-occlusive crisis (presence of sickle cell disease), ventricular arrhythmias

**EENT:** Blurred vision; change in color perception; diplopia; epistaxis; hearing loss; increased intraocular pressure; nasal congestion; nonarteritic anterior ischemic optic neuropathy (NAION); ocular burning, pressure, redness or swelling; paramacular edema; photophobia; retinal vascular bleeding or disease; tinnitus, visual decrease or temporary vision loss; vitreous detachment

**ENDO:** Uncontrolled diabetes mellitus

**GI:** Diarrhea, indigestion

**GU:** Cystitis, dysuria, painful erection, priapism, UTI

**MS:** Arthralgia, back pain

**RESP:** Pulmonary hemorrhage, upper respiratory tract infection

**SKIN:** Flushing, photosensitivity rash, urticaria

## Childbearing Considerations

### PREGNANCY

- Trade name, Viagra, is not indicated for use in females.
- It is not known if the trade name, Revatio, can cause fetal harm.
- Use Revatio with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Trade name, Viagra, is not indicated for use in females.
- Trade name, Revatio, appears to be present in breast milk.

- Patient should check with prescriber before breastfeeding if prescribed Revatio.

## Nursing Considerations

- Use sildenafil cautiously in the elderly and patients with hepatic or renal dysfunction, and men with penile abnormalities that may predispose them to priapism. In addition, use cautiously in patients who have suffered a life-threatening arrhythmia, myocardial infarction, or stroke within the last 6 months or in patients with cardiac failure, coronary artery disease causing unstable angina, hypertension (blood pressure greater than 170/110), related anemias, resting hypotension (blood pressure less than 90/50), retinitis pigmentosa, or sickle cell, as sildenafil therapy has not been studied in these patient groups.
- Also use cautiously in patients with left ventricular outflow obstruction, such as aortic stenosis and idiopathic hypertrophic subaortic stenosis, and those with severely impaired autonomic control of blood pressure because these conditions increase patient's sensitivity to vasodilators such as sildenafil.
- Reconstitute powder for oral suspension by tapping the bottle to release the powder, then remove the cap. Accurately measure out 60 ml of water and pour the water into the bottle, replace the cap, and shake the bottle vigorously for a minimum of 30 seconds. Solution should be clear and colorless and contain 10 mg sildenafil per 12.5 ml of solution. Store drug at room temperature. Discard any remaining oral suspension 60 days after constitution.
- Monitor patient's blood pressure and heart rate and rhythm before and often during therapy.
- Monitor vision, especially in patients over age 50; who have coronary artery disease, diabetes, hypertension, or hyperlipidemia; or who smoke, because, although rare, sildenafil may cause nonarteritic anterior ischemic optic neuropathy (NAION) that may lead to decreased vision or permanent vision loss. Patients at higher risk for NAION include those who have already experienced it in the past and those who have a low cup to optic disc ratio or retinitis pigmentosa.

**WARNING** Monitor patient being treated for pulmonary hypertension secondary to sickle cell disease for vaso-occlusive crisis (severe pain and change in color and

temperature if extremity is involved). Notify prescriber immediately and prepare to provide supportive care.

## PATIENT TEACHING

- Explain that sildenafil used to treat erectile dysfunction may be taken up to 4 hours before sexual activity, but that taking it 1 hour beforehand provides the most effective results.

**WARNING** Warn patient not to take sildenafil if he also takes any form of organic nitrate, either continuously or intermittently, or other PDE5 inhibitors, including REVATIO (a sildenafil product used to treat another condition), because profound hypotension and death could result. Also caution patient to inform prescriber of all medications taken as dosage may have to be decreased if a drug such as an alpha blocker has also been prescribed.

- Instruct patient prescribed oral suspension form how to mix it, store it, and discard any remaining suspension after 60 days. Stress importance of using the oral dosing syringe that accompanies the drug to measure dosage.
- Tell patient to stop taking drug and contact prescriber if vision decreases suddenly in one or both eyes or if he has a loss of hearing, possibly with dizziness or tinnitus.
- Advise patient taking sildenafil for erectile dysfunction to seek sexual counseling to enhance the drug's effects.
- Urge patient to notify prescriber immediately if erection is painful or lasts longer than 4 hours to avoid possible penile damage and permanent loss of erectile function.
- Instruct diabetic patient to monitor his blood glucose level frequently because drug may affect glucose control.

**silodosin**

# Rapaflo

## Class and Category

*Pharmacologic class:* Alpha adrenergic blocker

*Therapeutic class:* Benign prostatic antihyperplasia agent

## Indications and Dosages

➤ *To treat symptomatic benign prostatic hyperplasia*

### CAPSULES

**Adult men.** 8 mg daily with a meal. *Maximum:* 8 mg daily.

***DOSAGE ADJUSTMENT*** For patients with moderate renal impairment (creatinine clearance between 30 and 50 ml/min), dosage reduced to 4 mg daily.

## Mechanism of Action

Binds to postsynaptic  $\alpha_1$  adreno-receptors located in the bladder base and neck, prostate gland, and prostatic capsule and urethra. Blocking action at these adrenoceptor sites causes relaxation of smooth muscle in the local area, which improves urine flow and reduces other benign prostatic hyperplasia symptoms.

## Contraindications

Hypersensitivity to silodosin and its components, severe hepatic insufficiency (Child-Pugh score 10 or above), severe renal insufficiency (creatinine clearance less than 30 ml/min), use with alpha-blockers (doxazosin, prazosin,

terazosin) or strong CYP3A4 inhibitors (clarithromycin, ketoconazole, itraconazole, and ritonavir)

## Interactions

### DRUGS

*alpha blockers*: Possibly increased risk of orthostatic hypotension

*antihypertensives*: Increased risk of dizziness and orthostatic hypotension

*CYP3A4 inhibitors such as clarithromycin, diltiazem, erythromycin, itraconazole, ketoconazole, ritonavir; strong P-glycoprotein inhibitors such as cyclosporine*: Increased serum silodosin levels and risk of adverse reactions

## Adverse Reactions

**CNS**: Asthenia, dizziness, headache, insomnia, syncope

**CV**: Orthostatic hypotension

**EENT**: Nasal congestion, nasopharyngitis, rhinorrhea, sinusitis

**GI**: Abdominal pain, diarrhea, elevated liver enzymes, impaired hepatic function, jaundice

**GU**: Elevated prostate specific antigen level, retrograde ejaculation

**SKIN**: Pruritus, purpura, rash, **toxic skin eruption**, urticaria

**Other**: **Angioedema**

## Childbearing Considerations

### PREGNANCY

- Drug is not indicated for use in women.

## LACTAION

- Drug is not indicated for use in women.

## Nursing Considerations

- Use cautiously in patients with mild renal impairment and mild or moderate hepatic impairment. Patients with moderate renal impairment need dosage adjustment.
- Monitor patient's blood pressure for reduction, especially if he takes an antihypertensive with silodosin.

## PATIENT TEACHING

- Instruct patient to take drug with a meal.
- Tell patient who has difficulty swallowing capsules that he may carefully open the capsule and sprinkle the powder on a tablespoonful of applesauce and take within 5 minutes without chewing. He should then drink an 8-oz glass of cool water immediately afterward. Inform him that the applesauce should not be hot and it should be soft enough to be swallowed without chewing.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient planning cataract surgery or other ocular procedure to tell ophthalmologist that he takes silodosin or has taken it in the past because of potential adverse reactions.

**simeprevir**

**Olysio**

## Class and Category

*Pharmacologic class:* Protease inhibitor  
*Therapeutic class:* Antiviral

## Indications and Dosages

- *As adjunct to treat chronic hepatitis C virus (HCV) infection in patients with genotype 1 or 4 who are without cirrhosis or who have compensated cirrhosis*

### CAPSULES

**Adults.** 150 mg once daily with food for 12 wk; 24 wk in patients with genotype 1 infection taking sofosbuvir concomitantly and who also have compensated cirrhosis.

## Mechanism of Action

Inhibits the HCV NS3/4A protease, which is essential for viral replication.

## Contraindications

Hypersensitivity to simeprevir or its components

## Interactions

### DRUGS

*amiodarone:* Increased risk of serious symptomatic bradycardia when given in combination with sofosbuvir; increased plasma amiodarone level when used in a combination that does not contain sofosbuvir, increasing risk of adverse reactions

*atazanavir, fosamprenavir, indinavir, lopinavir, nelfinavir, saquinavir, sirolimus, tipranavir:* Change in plasma

simeprevir levels, either decreasing it and possibly decreasing its effectiveness, or increasing it and increasing risk of adverse reactions

*atorvastatin, fluvastatin, lovastatin, pitavastatin, pravastatin, rosuvastatin, simvastatin*: Increased risk of myopathy, including rhabdomyolysis

*calcium channel blockers, cisapride, cobicistat-containing products, disopyramide, flecainide, mexiletine, midazolam, milk thistle, propafenone, quinidine, triazolam*: Increased plasma concentrations of these drugs with increased risk of adverse reactions

*carbamazepine, dexamethasone, efavirenz, etravirine, nevirapine, oxcarbazepine, phenobarbital, phenytoin, rifabutin, rifampin, rifapentine, St. John's wort*: Decreased plasma concentration of simeprevir, possibly reducing its effectiveness

*clarithromycin, delavirdine, fluconazole, itraconazole, ketoconazole, posaconazole, ritonavir, telithromycin, voriconazole*: Increased plasma concentration of simeprevir, increasing risk of adverse reactions

*cyclosporine*: Increased plasma concentration of both drugs, increasing risk of adverse reactions

*darunavir/ritonavir*: Increased plasma levels of both darunavir and simeprevir, increasing risk of adverse reactions

*digoxin*: Increased risk of digitalis toxicity

*erythromycin*: Increased plasma levels of both erythromycin and simeprevir, increasing risk of adverse reactions

*ledipasvir*: Increased plasma levels of both ledipasvir and simeprevir, increasing risk of adverse reactions

*sildenafil, tadalafil*: Increased plasma levels of these drugs when used chronically at doses used for the treatment of pulmonary arterial hypertension, increasing risk of adverse reactions

*warfarin*: Possible fluctuations in INR values

## Adverse Reactions

**CNS:** Dizziness, fatigue, headache

**CV:** **Bradycardia (may become severe)**

**GI:** Diarrhea, elevated liver and pancreatic enzymes, **hepatic failure**, hyperbilirubinemia, nausea

**MS:** Myalgia

**RESP:** Dyspnea

**SKIN:** Photosensitivity, pruritus, rash

**Other:** Elevated alkaline phosphatase

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm. However, because drug is given in combination with ribavirin and peginterferon alfa, drug combination can cause fetal harm and is contraindicated in pregnant women and in men whose female partners are pregnant.
- Female patients and female partners of male patients must have a negative pregnancy test prior to drug therapy being initiated.

### LACTATION

- It is not known if drug is present in breast milk.
- Drug combination with ribavirin and peginterferon alfa is contraindicated during breastfeeding.

### REPRODUCTION

- Be aware that female patients or female partners of male patients must use at least two effective methods of contraception during combination treatment and for at least 6 months after drugs are discontinued.

- Female patients or female partners of male patients must undergo monthly pregnancy tests.

## Nursing Considerations

- Be aware that simeprevir should not be given to patients with moderate to severe hepatic impairment, because drug may cause hepatic decompensation and hepatic failure that may be fatal.
- Ensure that liver enzymes have been checked to provide a baseline of liver function prior to simeprevir use and then periodically as needed during simeprevir therapy. Closely monitor any patient who develops an increase in total bilirubin to greater than 2.5 times the upper limit of normal. Expect drug to be discontinued if any elevation in bilirubin is accompanied by elevated liver enzymes or signs and symptoms of hepatic decompensation.
- Know that patients with HCV genotype 1a infection containing the Q80K polymorphism should not be given simeprevir.
- Know that reducing the dosage of simeprevir or interrupting treatment should be avoided to prevent treatment failure. If treatment is discontinued because of adverse reactions or inadequate virologic response, know that simeprevir must not be restarted.

**WARNING** Ensure that all patients have been tested for current or prior HBV infection before simeprevir therapy is begun, because in patients coinfecting with HBV and HCV, there is risk of hepatitis B virus reactivation that may result in fulminant hepatitis, hepatic failure, or even death. If patient tests positive for HBV, monitor patient closely for clinical and laboratory signs, as ordered, of hepatitis flare or HBV reactivation during treatment with simeprevir and during posttreatment follow-up. Expect treatment for HBV infection to be given, if needed.

- Monitor patient also receiving amiodarone and sofosbuvir for symptomatic bradycardia that may be severe enough to require pacemaker intervention. Be aware that bradycardia may occur up to 2 weeks after simeprevir therapy has begun. Patients at risk include those taking beta

blockers or those with underlying advanced liver disease or cardiac disorders. Expect patient to be hospitalized for cardiac monitoring for the first 48 hours of simeprevir therapy. Notify prescriber if bradycardia occurs and expect drug to be discontinued. Known that bradycardia generally disappears after drug is discontinued.

- Assess patient's skin for a photosensitivity reaction that may appear as a severe sunburn or rash. These adverse reactions most often occur in the first 4 weeks of simeprevir therapy. If the photosensitivity reaction or rash is severe, expect drug to be discontinued. Know that patients at increased risk for these adverse reactions are patients with a sulfa allergy, because simeprevir contains a sulfonamide moiety.
- Monitor patient's HCV RNA levels, as ordered. Know that a sensitive assay with a lower limit of quantification of at least 25 IU/ml should be used. If patient experiences an inadequate virologic response at week 4, expect drug to be discontinued.

## **PATIENT TEACHING**

- Instruct patient to take simeprevir exactly as ordered and not to discontinue it without prescriber knowledge.
- Tell patient to take simeprevir every day at a regularly scheduled time with food.
- Teach patient how to take his pulse and to report immediately a sudden decrease in pulse rate or signs and symptoms of serious bradycardia, such as chest pain, confusion, dizziness, excessive tiredness, fainting or near-fainting, malaise, memory problems, shortness of breath, or weakness.
- Instruct patient to notify prescriber if she experiences signs and symptoms of liver dysfunction such as discolored stools, fatigue, lack of appetite, nausea, vomiting, weakness, or yellowing of skin or whites of the eyes.
- Warn patient to take sun-protective measures and limit sun exposure during simeprevir therapy. If a sunburn reaction occurs, tell patient to notify prescriber, as further monitoring of condition may be needed or simeprevir may have to be discontinued.
- Inform patient that a rash may occur within the first 4 weeks of therapy. Encourage him to notify prescriber so that the rash may be monitored for progression. If rash becomes severe, inform patient that the simeprevir will have to be discontinued.
- Tell patient to inform all prescribers of simeprevir therapy, because the drug reacts with many different drugs, which may cause reduced

effectiveness or increased risk of adverse reactions.

- Advise female patients to notify prescriber if pregnancy occurs or is suspected. If patient is also taking ribavirin with simeprevir, tell patient to use two reliable contraceptives during treatment and for at least 6 months after stopping ribavirin.
- Tell mothers wishing to breastfeed to discuss the benefits versus risks with their prescriber.

## simvastatin

**Zocor**

### Class and Category

*Pharmacologic class:* HMG-CoA reductase inhibitor (statin)

*Therapeutic class:* Antilipemic

### Indications and Dosages

➤ *To treat hyperlipidemia*

#### **TABLETS**

**Adults.** *Initial:* 10 or 20 mg daily in the evening. Dosage adjusted at 4-wk intervals, as needed, to achieve target LDL-cholesterol level. *Maintenance:* 5 to 40 mg daily.

➤ *To treat homozygous familial hypercholesterolemia; to reduce risk of cardiovascular events and coronary heart disease mortality in patients at high risk*

#### **TABLETS**

**Adults.** 40 mg daily in the evening. Dosage adjusted every 4 wk, as needed, to achieve target LDL-cholesterol level.

➤ *To treat adolescent heterozygous familial hypercholesterolemia*

## TABLETS

**Children ages 10 to 17 at least 1 year post-menarche.**

*Initial:* 10 mg daily in the evening. Adjusted every 4 wk, as needed, to achieve target LDL-cholesterol level.

*Maintenance:* 10 to 40 mg daily. *Maximum:* 40 mg daily.

**DOSAGE ADJUSTMENT** For patients with severe renal impairment, initial dosage reduced to 5 mg daily. For patients who are taking diltiazem, dronedarone, or verapamil, daily dosage should not exceed 10 mg; for patients who take amiodarone, amlodipine, or ranolazine, daily dosage should not exceed 20 mg. For patient taking lomitapide, daily dosage reduced by 50% and maximum dosage should not exceed 20 mg.

Route	Onset	Peak	Duration
P.O.	2 wk	4–6 wk	Unknown

## Mechanism of Action

Interferes with the hepatic enzyme hydroxymethylglutaryl-coenzyme A reductase. This action reduces the formation of mevalonic acid, a cholesterol precursor, thus interrupting the pathway necessary for cholesterol synthesis. When the cholesterol level declines in hepatic cells, LDLs are consumed, which in turn reduces the levels of circulating total cholesterol and serum triglycerides.

## Contraindications

Active hepatic disease; breastfeeding; concurrent use with concurrent use with strong CYP3A4 inhibitors such as boceprevir, clarithromycin, cobicistat-containing products, erythromycin, HIV protease inhibitors, itraconazole, ketoconazole, nefazodone, posaconazole, telaprevir, or telithromycin; concurrent use with cyclosporine, danazol, or gemfibrozil; hypersensitivity to simvastatin or its components; pregnancy

## Interactions

### DRUGS

*amiodarone, antiretroviral protease inhibitors boceprevir, calcium channel blockers (amlodipine, diltiazem, verapamil), cobicistat-containing products, clarithromycin, colchicine, cyclosporine, danazol, daptomycin, dronedarone, erythromycin, gemfibrozil and other fibrates, itraconazole, ketoconazole, nefazodone, niacin (1 g daily or more), posaconazole, ranolazine, telaprevir, telithromycin, voriconazole:* Increased risk of myopathy or rhabdomyolysis  
*digoxin:* Possibly slight elevation in blood digoxin level  
*oral anticoagulants:* Increased bleeding or prolonged PT

### FOODS

*grapefruit juice (1 or more quarts daily):* Increased risk of myopathy or rhabdomyolysis

## Adverse Reactions

**CNS:** Asthenia, cognitive impairment, dizziness, fatigue, headache, insomnia, vertigo

**CV:** **Atrial fibrillation**, chest pain, edema

**EENT:** Cataracts, rhinitis, sinusitis

**ENDO:** Elevated hemoglobin A<sub>1c</sub> levels, hyperglycemia

**GI:** Abdominal pain, constipation, diarrhea, elevated liver enzymes, flatulence, gastritis, heartburn, **hepatic failure**, indigestion, nausea, **pancreatitis**, vomiting

**GU:** Erectile dysfunction, UTI

**MS:** Immune-mediated necrotizing myopathy, myalgia, myopathy, **rhabdomyolysis**

**RESP:** Bronchitis, **interstitial lung disease**, upper respiratory tract infection

**SKIN:** Eczema, pruritus, rash

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Drug is contraindicated during pregnancy.
- Drug should be discontinued immediately when pregnancy becomes known.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

### REPRODUCTION

- Women of childbearing age should be advised to use effective contraception throughout drug therapy.

## Nursing Considerations

- Be aware concurrent therapy with niacin (greater than 1 g daily) and simvastatin is not recommended for use with Chinese patients.
- Use simvastatin cautiously in elderly patients and those with hepatic or renal impairment.
- Know that 80 mg of simvastatin should be used rarely, since it is associated with a high risk of myopathy. If 40 mg of simvastatin is not sufficiently efficacious, then an alternative agent should be used.
- Also, use cautiously in Chinese patients because of possible increased risk of myopathy.
- Give drug 1 hour before or 4 hours after giving bile acid sequestrant, cholestyramine, or colestipol.
- Monitor serum lipoprotein level, as ordered, to evaluate response to therapy.
- Expect to obtain liver enzymes prior to initiation of simvastatin therapy and then thereafter, as needed.
- Monitor patient for elevated CPK level (as ordered) or for muscle pain, tenderness, or weakness and other symptoms of myopathy; if left unchecked, the more serious form—rhabdomyolysis—may occur, which may lead to renal failure. Risk factors for myopathy include being 65 years or older, of female gender, and having renal impairment or uncontrolled hypothyroidism. If CPK level is significantly elevated or patient has symptoms of myopathy, notify prescriber and expect to withhold drug, as ordered.

## **PATIENT TEACHING**

- Urge patient to take drug in the evening.
- Urge patient to follow low-fat, cholesterol-lowering diet.
- Urge patient to notify prescriber immediately about muscle pain, tenderness, or weakness and other symptoms of myopathy and symptoms of abnormal liver function such as anorexia, dark urine, fatigue, right upper abdominal discomfort, or yellowing of skin.
- Inform female patient of childbearing age of need to use reliable contraceptive method while taking drug. Instruct her to notify prescriber at once if she suspects pregnancy.
- Advise patient to avoid grapefruit juice to decrease risk of drug toxicity.

- Inform patient with diabetes of need to test his blood sugar regularly and to obtain an HbA<sub>1c</sub> periodically.
- Encourage patient or family to notify prescriber if patient develops or exhibits confusion, forgetfulness, and worsening memory loss.
- Alert patient of increased risk for myopathy if he takes 80 mg of simvastatin daily.

# siponimod

## Mayzent

### Class and Category

*Pharmacologic class:* Sphingosine-1-phosphate (S1P) receptor modulator

*Therapeutic class:* Anti-inflammatory

### Indications and Dosages

- *To treat relapsing forms of multiple sclerosis, including active secondary progressive disease, clinically isolated syndrome, and relapsing-remitting disease*

#### **TABLETS**

**Adults with CYP2C9 genotypes \*1/\*1, \*1/\*2, or \*2/\*2.**

*Initial titration:* 0.25 mg once daily on days 1 and 2; 0.5 mg once daily on day 3; 0.75 mg once daily on day 4; and 1.25 mg once daily on day 5, followed by maintenance dose.

*Maintenance:* 2 mg once daily beginning on day 6.

**Adults with CYP2C9 genotypes \*1/\*3 and \*2/\*3.** Initial titration: 0.25 mg once daily on days 1 and 2; 0.5 mg once

daily on day 3; and 0.75 mg once daily on day 4, followed by maintenance dose. Maintenance: 1 mg once daily beginning on day 5.

**DOSAGE ADJUSTMENT** If one initial titration dose is missed for more than 24 hours, treatment reinitiated with day 1 of the titration regimen. If maintenance treatment is interrupted for 4 or more consecutive daily doses, treatment reinitiated with day 1 of titration regimen.

## Mechanism of Action

Binds with high affinity to S1P receptors 1 and 5. This blocks the capacity of lymphocytes to egress from lymph nodes, reducing the number of lymphocytes in peripheral blood and lymphocyte migration into the central nervous system.

## Contraindications

CVA; CYP2C9 \*3/\*3 genotype; decompensated heart failure requiring hospitalization; history within past 6 months of class III or IV heart failure; hypersensitivity to siponimod or its components; MI, TIA, or unstable angina; presence of Mobitz type II second-degree AV block, third-degree AV block, or sick sinus syndrome, unless a functioning pacemaker is in place

## Interactions

### DRUGS

*class 1a (procainamide, quinidine), class III (amiodarone, sotalol), drugs that decrease heart rate (digoxin, diltiazem, ivabradine, verapamil), QT prolongation drugs: Increased risk of bradycardia or torsades de pointes*

*antineoplastics, immune-modulating agents, immunosuppressants*: Increased risk of additive immune effects  
*beta blockers*: Additive lowering of heart rate  
*CYP2C9 inducers, CYP3A4 inducers*: Significant decrease in siponimod exposure  
*CYP2C9 inhibitors, CYP3A4 inhibitors*: Significant increase in siponimod exposure, increasing risk of adverse reactions  
*live attenuated vaccines*: Increased risk of infection  
*nonlive vaccines*: Possibly diminished therapeutic effect of vaccine

## Adverse Reactions

**CNS**: Asthenia, **CVA (ischemic)**, dizziness, falling, headache, **MI, seizures**, tremor

**CV**: AV block (1<sup>st</sup> or 2<sup>nd</sup> degree), **bradycardia**, hypertension, peripheral edema

**EENT**: Macular edema

**GI**: Diarrhea, elevated liver enzymes, nausea

**HEME**: Lymphopenia

**MS**: Extremity pain

**RESP**: Decreased pulmonary function, **pulmonary embolism**

**SKIN**: **Cutaneous malignancies**

**Other**: Herpes zoster, serious infections

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm, according to animal studies.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## REPRODUCTION

- Women of childbearing age should use an effective contraceptive throughout siponimod therapy and for 10 days following drug discontinuation.

## Nursing Considerations

- Use siponimod cautiously in patients with a history of significant liver disease because siponimod may affect liver function.
- Ensure that all of the following have been assessed before the initiation of siponimod therapy: complete blood count, CYP2C9 genotype determination, and liver function studies (bilirubin and transaminase levels within past 6 months). Also ensure that patient has had a cardiac examination (ECG, to determine whether preexisting conduction abnormalities are present), ophthalmic evaluation (including an evaluation of the fundus and the macula), current or prior medications (especially drugs that could slow heart rate or affect atrioventricular conduction); antineoplastics, immunosuppressives, or immune-modulating therapies that could cause additive immunosuppressive effects); and vaccinations (patient tested for antibodies to *varicella zoster* virus, with negative test results requiring vaccination prior to starting therapy).
- Know that with the first dose, 6-hour monitoring should be done, especially in patients with sinus bradycardia (heart rate less than 55 beats/minute) or first- or second-degree AV block and in patients with a history of heart failure or myocardial infarction. First dose should be administered in a setting to manage symptomatic bradycardia. Monitor patient for 6 hours after administering dose, with hourly blood pressure and pulse measurements. Obtain an ECG at the end of day 1. After day 1, determine if patient has any of the following abnormalities (even in the absence of symptoms) and continue monitoring patient until the abnormality resolves: heart rate 6 hours post dose is less than 45 beats per minute, heart rate 6 hours post dose is at the lowest value post dose, or ECG 6 hours post dose shows new-onset second-degree or higher AV block. If post-dose symptomatic bradycardia, bradyarrhythmia, or

conduction-related symptoms occur, if ECG 6 hours post dose shows new-onset second-degree or higher AV block, or QTc is greater than or equal to 500 msec, expect to initiate appropriate management, as ordered. Begin continuous ECG monitoring and continue monitoring patient until symptoms have resolved. If drug treatment is required, expect patient to be monitored overnight and the 6-hour monitoring period repeated after the second dose. Also, expect a consultation with a cardiologist to be ordered.

- Evaluate patient for signs and symptoms of an infection before siponimod therapy is begun. Review patient's recent CBC results. Know that drug should not be started in patients with a severe active infection until the infection is resolved. Also, be aware that patients should continue to be monitored for infection until at least 3 to 4 weeks after drug is discontinued. Provide treatment for an infection, as prescribed, and expect drug to be temporarily withheld if a serious infection develops. Know that life-threatening infections such as cryptococcal meningitis and disseminated cryptococcal infections have occurred, along with cases of herpes viral infection that may lead to varicella zoster meningitis. Although progressive multifocal leukoencephalopathy has not occurred with siponimod therapy, it has occurred in similar treatment modalities in patients with multiple sclerosis.
- Be aware that patients with a history of uveitis or who have diabetes mellitus are at increased risk of macular edema during siponimod therapy. Monitor patient for any visual changes.
- Monitor patient's liver enzymes, as ordered. Assess patient for signs and symptoms of liver dysfunction such as abdominal pain, anorexia, dark urine, fatigue, jaundice, nausea, rash, and vomiting. Report such findings to prescriber.
- Monitor patient's vital signs throughout siponimod therapy, as bradycardia and hypertension can occur along with conduction defects.
- Be aware of the possibility that posterior reversible encephalopathy syndrome may occur with siponimod therapy. Report any unexpected neurological or psychiatric signs and symptoms to prescriber. If disorder is suspected, expect drug to be discontinued.
- Monitor patient for severe increased disability after siponimod therapy has been discontinued. Although rare, stopping siponimod therapy may exacerbate multiple sclerosis and cause a disease rebound.
- Be aware that it may take up to 4 weeks after siponimod therapy is discontinued for the pharmacodynamic effects on the patient's immune system to end. During this time, caution should be used in prescribing immunosuppressants.

## PATIENT TEACHING

- Stress importance of taking siponimod exactly as prescribed. If a dose is missed for longer than 24 hours during the titration period, the period will have to be restarted with day 1 if maintenance doses are missed for more than 4 days, a titration period will have to be done again, including a first-dose 6-hour monitoring period.
- Prepare patient for the 6-hour monitoring period required for the first dose.
- Tell patient that any unopened containers of drug should be stored in the refrigerator. When opened, starter kits may be stored at room temperature for one week, and opened bottles may be stored at room temperature for one month.
- Review infection control measures with patient. Caution patient to avoid anyone with an infection.
- Warn patient to avoid receiving live attenuated vaccines while taking siponimod and for 4 weeks after drug is discontinued.
- Stress importance of having regular eye examinations during siponimod therapy and tell patient to report any visual changes to prescriber immediately.
- Advise patient to contact prescriber if new-onset or worsening dyspnea occurs.
- Review signs and symptoms of liver dysfunction with patient and tell him or her to contact prescriber if present.
- Tell patient that upon discontinuation of drug, a rebound effect may occur, exhibited by an exacerbation of the condition.
- Inform women of childbearing age of the possibility of fetal harm with drug therapy; instruct them to use effective contraception throughout therapy and for 10 days after drug is discontinued. Stress importance of reporting suspected or known pregnancy to prescriber at once.
- Advise patient that drug effects last for up to 4 weeks after drug is discontinued.

**sirolimus**

(rapamycin)

## Rapamune

### Class and Category

*Pharmacologic class:* Macrocyclic lactone

*Therapeutic class:* Immunosuppressant

### Indications and Dosages

➤ *To prevent rejection of kidney transplantation*

#### ORAL SOLUTION, TABLETS

**Adults weighing at high-immunologic risk.** *Initial:* up to 15 mg loading dose on day 1 post-transplantation.

*Maintenance:* 5 mg daily beginning on day 2 with dosage adjusted based on trough level taken between days 5 and 7, as needed, with further adjustments made, as needed, every 7 to 14 days. *Maximum:* 40 mg daily.

**Adults and adolescents weighing 40 kg (88 lb) or more at low- to moderate-immunologic risk.** *Initial:* 6-mg loading dose. *Maintenance:* 2 mg daily, with dosage adjusted according to trough levels, every 7 to 14 days, as needed. *Maximum:* 40 mg daily.

**Adolescents weighing less than 40 kg (88 lb) at low- to moderate-immunologic risk.** *Initial:* 3-mg/m<sup>2</sup> loading dose.

*Maintenance:* 1 mg/m<sup>2</sup> daily.

➤ *To treat lymphangiomyomatosis*

#### ORAL SOLUTION, TABLETS

**Adults.** 2 mg daily, dosage adjusted according to trough level 10 to 20 days later, then every 7 to 14 days, as needed, until a stable maintenance dose achieved.

Maintenance dosage

dosage adjustment reduced by one-third for patients with mild-to-moderate impaired hepatic function and one-half for patients with severe impaired hepatic function.

Maintenance dosage increased for patients discontinuing concomitant cyclosporine therapy.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	Up to 6 mo after discontinuation

## Mechanism of Action

Inhibits activation and proliferation of T lymphocytes and antibody production. Sirolimus also inhibits cell cycle progression from the G<sub>1</sub> to the S phase, possibly by inhibiting a key regulatory kinase believed to suppress cytokine-driven T-cell proliferation.

## Contraindications

Hypersensitivity to sirolimus or its components, malignancy

## Interactions

### DRUGS

*cyclosporine; strong CYP3A4 and P-gp inhibitors such as clarithromycin, erythromycin, itraconazole, ketoconazole, telithromycin, voriconazole; weak or moderate CYP3A4 and P-gp inhibitors such as bromocriptine, cimetidine, disaprider, clotrimazole, danazole, diltiazem, fluconazole, metoclopramide, nicardipine, protease inhibitors*

*(boceprevir, indinavir, ritonavir, telaprevir), troleandomycin, verapamil*: Increased sirolimus concentrations, increasing risk of adverse reactions  
*strong CYP3A4 and P-gp inducers such as rifabutin, rifampin; weak to moderate CYP3A4 and P-gp inducers such as carbamazepine, phenobarbital, phenytoin, rifapentine, St. John's Wort*: Decreased sirolimus concentrations, decreasing effectiveness  
*live vaccines*: Vaccination may be less effective  
*verapamil*: Increased concentrations of verapamil  
**DOSAGE ADJUSTMENT** Maintenance dosage reduced by one-third for patients with mild-to-moderate impaired hepatic function and one-half for patients with severe impaired hepatic function. Maintenance dosage increased for patients discontinuing concomitant cyclosporine therapy.

## FOODS

*grapefruit juice*: Possibly decreased metabolism of sirolimus

## Adverse Reactions

**CNS**: Asthenia, dizziness, fever, headache, insomnia, **posterior reversible encephalopathy syndrome**, **progressive multifocal leukoencephalopathy (PML)**, tremor

**CV**: **Atrial fibrillation**, chest pain, **deep vein thrombosis**, hyperlipidemia, hypersensitivity vasculitis, hypertension, hypertriglyceridemia, **pericardial effusion**, peripheral edema, **tachycardia**

**EENT**: Epistaxis, nasopharyngitis, stomatitis

**ENDO**: Hyperglycemia

**GI**: Abdominal pain, ascites, constipation, diarrhea, elevated liver enzymes, **hepatic artery thrombosis** (liver

transplant), **hepatotoxicity**, nausea, **pancreatitis**, vomiting

**GU:** Azoospermia, BK viral nephritis, elevated serum creatinine level, focal segmental glomerulosclerosis, **hemolytic uremic syndrome**, menstrual disorders, **nephrotic syndrome**, ovarian cysts, proteinuria, pyelonephritis, UTI

**HEME:** Anemia, **leukopenia**, **neutropenia**, **pancytopenia**, **thrombocytopenia**, **thrombocytopenic purpura**

**MS:** Arthralgia, bone necrosis, low back or flank pain, joint abnormality, myalgia

**RESP:** Alveolar proteinosis, **bronchial anastomotic dehiscence** (lung transplant), dyspnea on exertion, **interstitial lung disease**, pleural effusion, pneumonia, **pulmonary embolism or hemorrhage**, upper respiratory tract infection

**SKIN:** Acne, **cancer including melanoma and Merkel cell carcinoma**, **exfoliative dermatitis**, rash

**Other:** **Anaphylaxis**; **angioedema**; cytomegalovirus; delayed wound healing; Epstein-Barr virus; herpes simplex or zoster; **hypokalemia**; **hypophosphatemia**; increased susceptibility to infection, including opportunistic infections such as tuberculosis and activation of latent viral infections; lymphedema; lymphocele; **lymphoma**; **sepsis**; weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm.
- Drug should be discontinued immediately when pregnancy is known.

## **LACTATION**

- It is not known if drug is present in breast milk but due to drug's mechanism of action it may cause serious adverse effects in breastfed infants.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## **REPRODUCTION**

- Women of childbearing age should be advised to use effective contraception throughout drug therapy and for 12 weeks after drug has been discontinued.
- Both female and male fertility may be affected by drug use; females may develop menstrual disorders (including amenorrhea and menorrhagia) and ovarian cysts and males may develop azoospermia and oligospermia.

## **Nursing Considerations**

- Be aware that sirolimus isn't recommended in liver or lung transplant patients.
- Use sirolimus cautiously in patients who are receiving other drugs known to adversely affect renal function, such as aminoglycosides and amphotericin B; together, they may further decrease renal function.
- Monitor patients with existing or recent (including recent exposure to) chickenpox and patients with herpes zoster for worsening symptoms because they have an increased risk of developing severe generalized disease while taking sirolimus.
- Mix oral sirolimus with at least 2 oz (60 ml) of orange juice or water in a glass or plastic container. Don't dilute drug in grapefruit juice or any other liquid.
- Stir well and have patient drink solution immediately. Then rinse glass with at least 4 oz (120 ml) of additional liquid, stir well, and have patient drink that liquid to make sure that all of drug is taken.
- Give initial dose as soon after transplantation as possible and daily dose 4 hours after cyclosporine, as prescribed.

- Monitor whole blood sirolimus concentrations, as ordered, in patients receiving concentrated form of drug, patients with hepatic impairment or weighing less than 40 kg (88 lb), and those receiving potent CYP3A4 inducers or inhibitors concurrently.
- Know that when using trough level to determine drug's effectiveness, dosage adjustment should be made only after other factors are taken into account, such as signs, symptoms, and tissue biopsy findings. Keep in mind that interpretation methods vary among laboratories and values aren't interchangeable.
- Monitor serum creatinine level, as ordered, because BK virus-associated nephropathy has occurred with sirolimus therapy. In addition, patients receiving sirolimus and cyclosporine may develop impaired renal function. Notify prescriber of any increases in serum creatinine level because sirolimus or cyclosporine dosage may have to be adjusted or drug discontinued.
- Monitor patient for urinary protein excretion, as ordered. If protein appears in urine, sirolimus may have to be discontinued.
- Monitor patient for signs and symptoms of infection and check CBC results, as ordered, to detect sirolimus-induced blood dyscrasias or changes in neutrophil count, which may indicate infection.
- Keep in mind for patients with hyperlipidemia, of the potential need to institute dietary changes, an exercise program, or a lipid-lowering drug regimen if blood cholesterol or triglyceride levels increase because drug may aggravate hyperlipidemia.
- Monitor patients with wounds who are taking sirolimus because drug may impair or delay wound healing, especially in patients with a body mass index greater than 30 kg/m<sup>2</sup>.

## **PATIENT TEACHING**

- Advise patient to take sirolimus consistently either with or without food (but not food high in fat) to prevent changes in absorption rate.
- Advise patient prescribed tablet form not to chew, crush, or split the tablets but to take whole.
- Instruct patient to take daily dose with at least 2 oz (60 ml) of orange juice or water. Caution him not to dilute drug in grapefruit juice or any other liquid. Advise him to stir mixture well and drink immediately, then to add at least another 4 oz (120 ml) of liquid to empty container, stir mixture again, and drink that liquid to ensure that he has swallowed all of drug.

- Urge patient to avoid people with cold, flu, or other infections because immunosuppression makes him more vulnerable.
- Instruct patient not to take live vaccines, during sirolimus therapy.
- Inform patient that sirolimus therapy may increase his risk of skin cancer. Tell him to avoid prolonged sun exposure, sun lamps, and tanning booths. He should use a sunscreen with a high protection factor and wear protective clothing when outdoors.
- Advise patient to keep follow-up appointments for blood tests, as ordered.
- Advise women of childbearing age that sirolimus may be harmful to unborn child. Stress importance of using an effective contraceptive before therapy starts, throughout therapy, and for 12 weeks after therapy is ended. If pregnancy does occur, instruct patient to notify prescriber immediately.

## sitagliptin phosphate

**Januvia**

### Class and Category

*Pharmacologic class:* Dipeptidyl peptidase-4 (DPP-4) inhibitor

### Indications and Dosages

- *As adjunct to achieve control of glucose level in type 2 diabetes mellitus*

#### **TABLETS**

**Adults.** 100 mg once daily.

***DOSAGE ADJUSTMENT*** For patients with moderate renal insufficiency (estimated glomerular filtration rate of 30

ml/min to less than 45 ml/min), dosage reduced to 50 mg once daily; for patients with severe renal insufficiency (estimated glomerular filtration rate less than 30 ml/min) or end-stage renal disease requiring hemodialysis or peritoneal dialysis, dosage reduced to 25 mg once daily.

Route	Onset	Peak	Duration
P.O.	Unknown	1–4 hr	Unknown

## Mechanism of Action

Inhibits the dipeptidyl peptidase-4 enzyme to slow inactivation of incretin hormones. These hormones are released by the intestine throughout the day but increase in response to a meal. When blood glucose level is normal or increased, incretin hormones increase insulin synthesis and release from pancreatic beta cells. One type of incretin hormone, glucagon-like peptide (GLP-1) also lowers glucagon secretion from pancreatic alpha cells, which reduces hepatic glucose production. These combined actions decrease blood glucose level in type 2 diabetes.

## Contraindications

Hypersensitivity to sitagliptin or its components

## Interactions

### DRUGS

*digoxin*: Slightly increased plasma digoxin level

*insulin or insulin secretagogue such as sulfonylureas*:

Possibly increased hypoglycemic effects

# Adverse Reactions

**CNS:** Headache

**CV:** **Heart failure**

**EENT:** Mouth ulceration, nasopharyngitis, stomatitis

**GI:** Abdominal pain, **acute pancreatitis**, constipation, diarrhea, elevated liver enzymes, nausea, vomiting

**GU:** **Acute renal failure**, worsening renal function

**RESP:** Upper respiratory tract infection

**MS:** Arthralgia (disabling, severe), back or extremity pain, myalgia

**SKIN:** Bullous pemphigoid, cutaneous vasculitis, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** **Anaphylaxis**, **angioedema**

# Childbearing Considerations

## PREGNANCY

- Pregnancy exposure registry: 1-800-986-8999.
- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Assess patient's renal function before starting sitagliptin therapy, as ordered, and periodically thereafter. In moderate to severe renal dysfunction, dosage will be reduced and frequency of assessing renal

function increased. Also know that renal function should be assessed more frequently in elderly patients because aging can be associated with reduced renal function.

- Monitor patient for hypersensitivity reactions that, although uncommon, may be severe. If present, notify prescriber and expect sitagliptin to be discontinued.
- Monitor patient's blood glucose level, as ordered, to determine effectiveness of sitagliptin therapy.
- Be aware that heart failure has occurred with two other drugs in the same class as sitagliptin. Monitor patient for signs and symptoms of heart failure and if present report immediately to prescriber; provide care according to standard protocols, as ordered; and know that sitagliptin may have to be discontinued.

## **PATIENT TEACHING**

- Emphasize the need to follow a diet control program and an exercise program during sitagliptin therapy.
- Warn patient not to chew, crush, or split the tablet before swallowing.
- Advise patient to notify prescriber immediately if she has trouble breathing, or has hives, rash, or swelling.
- Inform patient that periodic blood tests will be done to determine effectiveness of drug and to assess kidney function.
- Teach patient how to monitor blood glucose level and when to report changes.
- Caution patient that taking other drugs in addition to sitagliptin to control his diabetes or taking certain drugs to treat other conditions may lead to hypoglycemia. Review signs, symptoms, and appropriate prescribed treatment for hypoglycemia with him.
- Instruct patient to contact prescriber if he develops other illnesses, such as infection, or experiences surgery or trauma because his diabetes medication may require adjustment.
- Advise patient to carry identification indicating that she has diabetes.
- Instruct patient to stop taking sitagliptin and report persistent severe abdominal pain, possibly radiating to the back and accompanied by vomiting.

- Review signs and symptoms of heart failure, such as rapid weight increase, shortness of breath, or swelling in feet. Instruct patient to immediately report such to prescriber.
- Tell patient to report development of blisters or erosions while receiving sitagliptin therapy.

## sodium bicarbonate

### Baking Soda, Sellymin (CAN)

## Class and Category

*Pharmacologic class:* Electrolyte

*Therapeutic class:* Antacid, electrolyte replenisher, systemic and urinary alkalizer

## Indications and Dosages

➤ *To treat hyperacidity*

### ORAL POWDER

**Adults and adolescents.** One-half teaspoon mixed in at least 120 ml of water every 2 hr, as needed. *Maximum:* 4 teaspoons daily.

### TABLETS

**Adults and adolescents.** 325 mg to 2 g daily to four times a day, as needed. *Maximum:* 16 g daily.

**Children ages 6 to 12.** 520 mg, repeated once after 30 min, as needed.

- *To provide urinary alkalization*

## ORAL POWDER

**Adults and adolescents.** 1 teaspoon mixed in at least 120 ml of water every 4 hr. *Maximum:* 4 teaspoons daily.

## TABLETS

**Adults and adolescents.** *Initial:* 4 g, then 1 to 2 g every 4 hr. *Maximum:* 16 g daily.

**Children.** 23 to 230 mg/kg daily, adjusted as needed.

- *To treat metabolic acidosis or to treat certain drug intoxications such as barbiturate, methyl alcohol, and salicylate toxicity*

## I.V. INJECTION

**Adults in cardiac arrest.** *Initial:* 44.6 to 100 mEq followed by 44.6 to 50 mEq every 5 to 10 min, if needed.

## I.V. INFUSION

**Adults with less urgent forms of metabolic acidosis.** *Initial:* 2 to 5 mEq/kg given over a 4 to 8 hour period followed by reduction in dose and frequency, if needed.

***DOSAGE ADJUSTMENT*** Dosage reduction possible for elderly patients because of age-related renal impairment.

## Mechanism of Action

Buffers excess hydrogen ions, increases plasma bicarbonate level, and raises blood pH, thereby reversing metabolic acidosis. Sodium bicarbonate also increases the excretion of free bicarbonate ions in urine, raising urine pH; increased alkalinity of urine may help to dissolve uric

acid calculi. In addition, it relieves symptoms of hyperacidity by neutralizing or buffering existing stomach acid, thereby increasing the pH of stomach contents.

## Incompatibilities

Do not add dobutamine or norepinephrine to solution containing sodium bicarbonate as these drugs are incompatible with sodium bicarbonate. Also, do not add sodium bicarbonate to parenteral solutions containing calcium as a precipitation or haze may develop. Do not add other drugs in the same solution containing sodium bicarbonate or through same I.V. line as compatibility is unknown.

## Contraindications

Loss of chloride through vomiting or continuous gastrointestinal suction, use of diuretic therapy known to produce a hypochloremic alkalosis

## Interactions

### DRUGS

*amphetamines, quinidine*: Decreased urinary excretion of these drugs, possibly resulting in toxicity

*calcium-containing products*: Increased risk of milk-alkali syndrome

*ciprofloxacin, norfloxacin, ofloxacin*: Decreased solubility of these drugs, leading to crystalluria and nephrotoxicity

*citrates*: Increased risk of systemic alkalosis; increased risk of calcium calculus formation and hypernatremia in patients with history of uric acid calculi

*digoxin*: Possibly elevated digoxin level

*H<sub>2</sub>-receptor antagonists, iron preparations or supplements, ketoconazole*: Decreased absorption of these drugs  
*urinary acidifiers (ammonium chloride, ascorbic acid, potassium and sodium phosphates)*: Counteracted effects of urinary acidifiers

## **FOODS**

*dairy products*: Increased risk of milk-alkali syndrome with prolonged use of sodium bicarbonate

## **Adverse Reactions**

**CNS**: Mental or mood changes

**CV**: **Irregular heartbeat**, peripheral edema (with large doses), weak pulse

**EENT**: Dry mouth

**GI**: Abdominal cramps, thirst

**MS**: Muscle spasms, myalgia

**SKIN**: Extravasation with necrosis, tissue sloughing, or ulceration

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Be aware that drug increases risk of metabolic acidosis and edema in pregnant women.

### **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Monitor sodium intake of patient taking sodium bicarbonate oral powder contains 952 mg of sodium/tsp; and tablets contain 325 mg/3.9-mEq tablet, 520 mg/6.2-mEq tablet, and 650 mg/7.7-mEq tablet.
- For I.V. infusion, dilute drug with D<sub>5</sub>W, normal saline solution, or other standard electrolyte solution before administration.
- Avoid rapid I.V. infusion, which can cause severe alkalosis. Be aware that during cardiac arrest, risk of death from acidosis may outweigh risks of rapid infusion.
- Monitor urine pH, as ordered, to determine drug's effectiveness as urine alkalizer.
- Know that if patient on long-term sodium bicarbonate therapy is consuming calcium or milk, watch for milk-alkali syndrome, characterized by anorexia, confusion, headache, hypercalcemia, metabolic acidosis, nausea, renal insufficiency, and vomiting.
- Be aware that parenteral forms are hypertonic and that increased sodium intake can produce edema and weight gain.
- Assess I.V. site often for evidence of extravasation. If it occurs, notify prescriber at once and remove I.V. catheter. Elevate the limb, apply warm compresses, and expect prescriber to administer a local injection of hyaluronidase or lidocaine.

## **PATIENT TEACHING**

- Advise patient not to take sodium bicarbonate with large amounts of dairy products or for longer than 2 weeks, unless directed by prescriber.
- Caution patient not to take more drug than prescribed to avoid adverse reactions.
- Direct patient not to take drug within 2 hours of other oral drugs.
- Advise patient to avoid taking other prescribed or OTC drugs without prescriber's approval because many drugs interact with sodium bicarbonate.

# sodium ferric gluconate

***(contains 62.5 mg elemental iron per 5 ml)***

**Ferrlecit**

## Class and Category

*Pharmacologic class:* Iron salt, mineral

*Therapeutic class:* Hematinic

## Indications and Dosages

- *To treat iron deficiency anemia in patients receiving long-term hemodialysis and supplemental epoetin therapy*

## I.V. INFUSION OR INJECTION

**Adults.** 10 ml (125 mg of elemental iron.) diluted in 100 ml of 0.9% sodium chloride and infused over 1 hr per dialysis session or injected undiluted slowly at a rate of up to 12.5 mg/min per dialysis session. *Maximum:* 125 mg per dose.

*Usual:* Minimum cumulative dose of 1 g elemental iron given over eight sequential dialysis treatments. Dosage repeated at lowest dosage needed to maintain target levels of hemoglobin and hematocrit and acceptable limits of blood iron level.

*Children age 6 and over.* 0.12 ml/kg (1.5 mg/kg of elemental iron) diluted in 25 ml of 0.9% sodium chloride

infused over 1 hr per dialysis session. *Maximum:* 125 mg per dose.

## **Mechanism of Action**

Acts to replenish iron stores lost during hemodialysis as a result of increased blood loss or increased iron utilization from epoetin therapy. Iron is an essential component of hemoglobin, myoglobin, and several enzymes, including catalase, cytochromes, and peroxidase, and is needed for catecholamine metabolism and normal neutrophil function. Sodium ferric gluconate also normalizes RBC production by binding with hemoglobin or being stored as ferritin in reticuloendothelial cells of the bone marrow, liver, and spleen.

## **Incompatibilities**

Don't mix sodium ferric gluconate with other drugs or parenteral nutrition solutions for I.V. infusion.

## **Contraindications**

Hypersensitivity to sodium ferric gluconate or its components

## **Interactions**

### **DRUGS**

*oral iron preparations:* Possibly reduced absorption of oral iron supplements

## **Adverse Reactions**

**CNS:** Asthenia, dizziness, fatigue, fever, headache, hypertonia, nervousness, paresthesia, syncope

**CV:** Chest pain, generalized edema, hypertension, **hypotension**, tachycardia

**EENT:** Dry mouth

**GI:** Abdominal pain, diarrhea, nausea, vomiting

**HEME:** **Hemorrhage**

**MS:** Back pain, leg cramps

**RESP:** Cough, dyspnea, upper respiratory tract infection, wheezing

**SKIN:** Diaphoresis, pruritus

**Other:** **Anaphylaxis**, generalized pain, **hyperkalemia**, **hypersensitivity reactions**, infusion or injection-site reaction

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm under certain circumstances, especially in the second and third trimesters. For instance, drug may cause circulatory failure in mother, which in turn causes bradycardia in the fetus.
- Be aware that drug also contains benzyl alcohol, which does not appear to have an effect on fetus through maternal drug administration; however, it can cause serious adverse events and death when administered intravenously to neonates and infants.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk. However, benzyl alcohol is possibly present in breast milk and may be transferred to neonate during breastfeeding.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Reconstitute sodium ferric gluconate for I.V. infusion by diluting prescribed dosage in 100 ml of normal saline solution immediately before infusion. Infuse over 1 hour. Discard any unused diluted solution.
- Inspect drug for discoloration and particles before administration and discard if present.
- Give undiluted drug by slow I.V. injection at up to 12.5 mg/min, not to exceed 125 mg/injection.
- Be aware that most patients need a minimum cumulative dose of 1 g of elemental iron administered over eight sequential dialysis treatments.

**WARNING** Assess patient for evidence of allergic reaction, including chills, facial flushing, pruritus, and rash, and of a hypersensitivity reaction, including diaphoresis, dyspnea, nausea, severe lower back pain, vomiting, and wheezing. Discontinue drug and notify prescriber immediately if patient develops an allergic or hypersensitivity reaction, and be prepared to provide emergency interventions.

**WARNING** Assess blood pressure often after drug administration because hypotension may occur and may be related to infusion rate or total cumulative dose. Avoid rapid infusion, and be prepared to provide I.V. fluids for volume expansion.

- Expect to monitor blood hemoglobin level, hematocrit, serum ferritin level, and transferrin saturation, as ordered, before, during, and after sodium ferric gluconate therapy. Make sure serum iron level is tested 48 hours after last dose. To prevent iron toxicity, notify prescriber and expect to end therapy if blood iron level is normal or elevated.
- Assess patient for possible iron overload, characterized by bleeding in GI tract and lungs, decreased activity, pale conjunctivae, and sedation.

## PATIENT TEACHING

- Warn patient not to take any oral iron preparations during sodium ferric gluconate therapy without first consulting prescriber.
- Inform patient that symptoms of iron deficiency may include decreased stamina, fatigue, learning problems, and shortness of breath.

## sodium polystyrene sulfonate

**Kalexate, Kayexalate, K-Exit (CAN), Kionex, SPS Suspension**

### Class and Category

*Pharmacologic class:* Sulfonated cation-exchange resin

*Therapeutic class:* Antihyperkalemic

### Indications and Dosages

➤ *To treat hyperkalemia*

#### ORAL POWDER, SUSPENSION

**Adults.** 15 g (4 level tsp) once daily to four times a day.

#### RECTAL POWDER, SUSPENSION

**Adults.** 30 to 50 g every 6 hr as retention enema, as needed.

Route	Onset	Peak	Duration
P.O.	2-12 hr	Unknown	Unknown

# Mechanism of Action

Releases sodium ions in exchange for other cations in intestines. Resin enters large intestine and releases sodium ions in exchange for hydrogen ions. As the resin moves through the intestines, hydrogen ions are then exchanged for potassium ions, which are in greater concentration. Bound resin leaves the body in feces, carrying potassium and other ions with it, thereby reducing serum potassium level.

# Contraindications

Hypersensitivity to sodium polystyrene sulfonate or its components, hypokalemia, obstructive bowel disease, reduced intestinal motility in neonates

# Interactions

## DRUGS

*nonabsorbable cation-donating antacids and laxatives:*  
Reduced resin's potassium exchange capability, increased risk of systemic alkalosis

*sorbitol:* May contribute to risk of intestinal necrosis by sorbitol

*other orally administered medications:* Decreased absorption and reduced effectiveness of these drugs

# Adverse Reactions

**CV:** Peripheral edema

**GI:** Abdominal cramps, anorexia, **colonic necrosis**, constipation, diarrhea, epigastric pain, fecal impaction, gastric irritation, **GI bleeding**, indigestion, **intestinal**

**necrosis or obstruction, ischemic colitis**, nausea, ulcerations, vomiting

**GU:** Decreased urine output

**RESP:** Aspiration

**Other:** **Hypernatremia, hypocalcemia, hypokalemia, hypomagnesemia, metabolic alkalosis**, weight gain

## Childbearing Considerations

### PREGNANCY

- Drug is not absorbed systemically and is not expected to cause fetal harm.

### LACTATION

- Drug is not present in breast milk, as it is not absorbed systemically and is not expected to pose harm to breastfed infant.

## Nursing Considerations

- Know that sodium polystyrene sulfonate should not be given to a patient who has not had a bowel movement postsurgery, or in patients who are at risk for developing constipation or impaction (including patients with a history of chronic constipation, inflammatory bowel disease, impaction, ischemic colitis, previous bowel obstruction or resection, or vascular intestinal atherosclerosis) because these factors increase the risk for intestinal necrosis, which may be life-threatening.
- Use sodium polystyrene sulfonate cautiously in patients with heart failure, hypertension, or marked edema.
- Be aware that drug is available as powdered resin or as solution that contains sorbitol to facilitate movement of resin through intestines. As a result, patient may experience abdominal cramps, diarrhea, nausea, and vomiting.
- Be aware that because the drug doesn't take effect for several hours it's inappropriate for treating acute, life-threatening hyperkalemia.

- Assess patient for hypokalemia or hypocalcemia. If present, notify prescriber immediately and expect to withhold drug because it reduces calcium and potassium levels. Evidence of hypokalemia includes abdominal cramps, acidic urine, anorexia, drowsiness, ECG changes, hypotension, hypoventilation, muscle weakness, and tachycardia. Evidence of hypocalcemia includes abdominal pain, agitation, anxiety, ECG changes, hypotension, muscle twitching, psychosis, seizures, and tetany.
- Mix powdered resin to be given as oral suspension in food, syrup, or water and give promptly, being sure to follow full aspiration precautions (such as keeping patient in an upright position while giving drug), because patients may be at risk of aspiration caused by inhalation of sodium polystyrene sulfonate particles, especially patients with altered level of consciousness, impaired gag reflex, or who are prone to regurgitation. If needed, administer through gastric feeding tube.
- Administer other oral medication at least 3 hours before or 3 hours after sodium polystyrene sulfonate administration, because drug may interfere with the absorption of other orally administered medications. However, patients with gastroparesis may require a 6-hour separation.
- Precede rectal administration with a cleansing enema, as ordered.
- Know that when giving rectally, powdered resin in 100 ml of aqueous solution should be warmed to body temperature, in bag connected to soft, large (French 28) catheter. Have patient lie on his left side with his lower leg straight and upper leg flexed or with his knees to his chest. Gently insert the tube into the rectum and well into the sigmoid colon. The solution should flow into the colon by way of gravity and be retained for 30 to 60 minutes or longer, if possible. After patient is unable to retain the solution any longer, administer a non-sodium-containing cleansing enema, as prescribed.
- Use of sorbitol with sodium polystyrene sulfonate isn't recommended because of increased risk of colonic necrosis and other serious GI effects, such as bleeding, ischemic colitis, and perforation.
- Assess for constipation and fecal impaction after administration. If either occurs, notify prescriber, expect drug to be discontinued, and provide care, as ordered, to relieve constipation or fecal impaction.

## **PATIENT TEACHING**

- Instruct patient not to mix oral form of sodium polystyrene sulfonate with foods and liquids high in potassium content, such as bananas and orange juice.

- Teach patient who will self-administer rectal solution, the correct technique and body position. Remind him to let the solution flow into the colon by gravity and to retain it for at least 30 to 60 minutes, longer if possible.
- Advise patient to notify prescriber immediately about abdominal cramps, nausea, and vomiting.

## sodium zirconium cyclosilicate

**Lokelma**

### Class and Category

*Pharmacologic class:* Potassium binder

*Therapeutic class:* Potassium reducer

### Indications and Dosages

➤ *To treat hyperkalemia in nonlife-threatening situations*

#### ORAL SUSPENSION

**Adults.** *Initial:* 10 g three times daily for up to 48 hr.

*Maintenance:* 10 g once daily. Dosage increased during maintenance in increments of 5 g at weekly or longer intervals, as needed, based on serum potassium.

### Mechanism of Action

Increases fecal potassium excretion through binding of potassium in the lumen of the gastrointestinal tract. This

reduces the concentration of free potassium in the gastrointestinal lumen, thereby lowering serum potassium levels.

## Contraindications

Hypersensitivity to sodium zirconium cyclosilicate or its components

## Interactions

### DRUGS

*oral drugs that have pH-dependent solubility:* Altered absorption of these drugs, possibly causing altered efficacy or safety

## Adverse Reactions

CV: Edema

Other: **Hypokalemia**

## Childbearing Considerations

### PREGNANCY

- Drug is not absorbed systemically and is not expected to affect the fetus.

### LACTATION

- Drug is not absorbed systemically and is not expected to be present in breast milk.

## Nursing Considerations

- Know that sodium zirconium cyclosilicate should not be given to patients with abnormal postoperative bowel motility disorders, bowel obstruction, bowel impaction, or severe constipation, because drug may be ineffective or even worsen these gastrointestinal conditions.
- Empty entire contents of packet into a drinking glass containing about 3 tablespoons of water or more, if patient desires. Stir well and administer immediately. If powder remains in the drinking glass, add water, stir, and have patient drink immediately. Repeat until no powder remains, to ensure that entire dose has been given.
- Administer other oral drugs at least 2 hours before or after sodium zirconium cyclosilicate administration to prevent other drugs from not being absorbed properly.
- Monitor patient for edema, especially patients who should restrict their sodium intake or are prone to fluid retention, such as those with heart failure or renal disease.

## **PATIENT TEACHING**

- Tell patient to empty entire contents of packet into a drinking glass containing about 3 tablespoons of water or more, if patient desires. Tell patient to stir well and drink immediately. If powder remains in the drinking glass, patient should add water, stir, and drink contents immediately. Repeat until no powder remains, to ensure that entire dose has been given.
- Instruct patient to take other oral drugs at least 2 hours before or after sodium zirconium cyclosilicate administration, to prevent other drugs from not being absorbed properly.
- Advise patient to limit dietary sodium intake, if needed, and to notify prescriber if fluid retention occurs.

**sofosbuvir**

**Sovaldi**

# Class and Category

*Pharmacologic class:* NS5B polymerase inhibitor

*Therapeutic class:* Antiviral

## Indications and Dosages

- *As adjunct to treat chronic hepatitis C virus (HCV) infection in patients with genotype 1 or 4 who are without cirrhosis or who have compensated cirrhosis and used in combination with pegylated interferon and ribavirin*

### **TABLETS**

**Adults who are treatment-naïve.** 400 mg once daily for 12 wk.

- *As adjunct to treat chronic hepatitis C virus (HCV) infection in patients with genotype 2 or 3 who are without cirrhosis or who have compensated cirrhosis and used in combination with ribavirin*

### **ORAL PELLETS, TABLETS**

**Adults and children age 3 years and over weighing at least 35 kg (77 lb).** 400 mg once daily for 12 wk for genotype 2 and 24 wk for genotype 3.

**Children age 3 years and over weighing 17 to less than 35 kg (37.4 to 77 lb).** 200 mg once daily for 12 wk for genotype 2 and 24 wk for genotype 3.

**Children age 3 years and over weighing less than 17 kg (37.4 lb).** 150 mg once daily for genotype 2 and 24 wk for genotype 3.

- *As adjunct to treat chronic hepatitis C virus (HCV) infection in patients with hepatocellular carcinoma*

*waiting for a liver transplant in combination with ribavirin*

## **TABLETS**

**Adults.** 400 mg once daily for 48 wk or until liver transplant.

## **Mechanism of Action**

Undergoes intracellular metabolism to form an active uridine analogue triphosphate, which is then incorporated into HCV RNA by the NS5B polymerase and acts as a chain terminator.

## **Contraindications**

Hypersensitivity to sofosbuvir or its components

## **Interactions**

### **DRUGS**

*amiodarone:* Possibly development of serious symptomatic bradycardia

*carbamazepine, oxcarbazepine, phenobarbital, phenytoin, rifabutin, rifampin, rifapentine, St. John's wort,*

*tipranavir/ritonavir:* Possibly decreased sofosbuvir plasma concentration, leading to reduced effectiveness

## **Adverse Reactions**

**CNS:** Asthenia, chills, depression (severe), fatigue, fever, headache, insomnia, irritability, **suicidal ideation**

**GI:** Anorexia, diarrhea, elevated pancreatic enzymes, hyperbilirubinemia, nausea

**HEME:** Anemia, **neutropenia**, **pancytopenia**, **thrombocytopenia**

**MS:** Elevated creatine kinase, myalgia

**SKIN:** Pruritus, rash (sometimes with blisters or angioedema-like swelling)

**Other:** **Angioedema**, flu-like symptoms

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm. However because drug is given in combination with ribavirin or peginterferon alfa and ribavirin, drug combinations can cause fetal harm and are contraindicated in pregnant women and in men whose female partners are pregnant.
- Female patients and female partners of male patients must have a negative pregnancy test prior to drug therapy being initiated.

### LACTATION

- It is not known if drug is present in breast milk.
- Drug combinations with ribavirin or peginterferon alfa and ribavirin make breastfeeding contraindicated.

### REPRODUCTION

- Be aware that female patients or female partners of male patients must use at least two effective methods of contraception during combination treatment and for at least 6 months after drugs are discontinued.
- Female patients and female partners of male patients must undergo monthly pregnancy tests.

## Nursing Considerations

- Know that reducing the dosage of sofosbuvir or interrupting treatment should be avoided to prevent treatment failure. Also be aware that if other drugs used in combination with sofosbuvir are discontinued, sofosbuvir should also be discontinued.

**WARNING** Ensure that all patients have been tested for current or prior HBV infection before sofosbuvir therapy is begun, because in patients coinfecting with HBV and HCV, there is risk of hepatitis B virus reactivation that may result in fulminant hepatitis, hepatic failure, or even death. If patient tests positive for HBV, monitor patient closely for clinical and laboratory signs, as ordered, of hepatitis flare or HBV reactivation during treatment with sofosbuvir and during posttreatment follow-up. Expect treatment for HBV infection to be given, if needed.

- Monitor patient also receiving amiodarone with sofosbuvir for symptomatic bradycardia that may be severe enough to require pacemaker intervention. Be aware that bradycardia may occur up to 2 weeks after sofosbuvir therapy has begun. Patients at risk include those taking beta blockers or those with underlying advanced liver disease or cardiac disorders. Expect patient to be hospitalized for cardiac monitoring for the first 48 hours of sofosbuvir therapy. Notify prescriber if bradycardia occurs and expect drug to be discontinued. Known that bradycardia generally disappears after the drug is discontinued.

## **PATIENT TEACHING**

- Instruct patient to take sofosbuvir exactly as ordered and not to discontinue it without prescriber knowledge.
- Tell patient to take sofosbuvir every day at a regularly scheduled time.
- Instruct children taking oral pellet form not to chew the pellets. Tell parents pellets can be administered with food by sprinkling the pellets on one or more spoonfuls of nonacidic foods such as chocolate syrup, ice, cream, mashed potato, or pudding and gently mixing. The mixture should be consumed within 30 minutes and not chewed to avoid a bitter aftertaste.

- Teach patient how to take his pulse and to report immediately a sudden decrease in pulse rate or signs and symptoms of serious bradycardia, such as chest pain, confusion, dizziness, excessive tiredness, fainting or near-fainting, malaise, memory problems, shortness of breath, or weakness.
- Tell patient to inform all prescribers of sofosbuvir therapy, because the drug reacts with many different drugs, which may cause reduced effectiveness or increased risk of adverse reactions.
- Advise female patients to notify prescriber if pregnancy occurs or is suspected. If patient is also taking ribavirin with sofosbuvir, tell patient to use two reliable contraceptives during treatment and for at least 6 months after stopping ribavirin.
- Tell mothers wishing to breastfeed to discuss the benefits versus risks with their prescriber.

## solifenacin succinate

**VESIcare**

### Class and Category

*Pharmacologic class:* Antimuscarinic

*Therapeutic class:* Bladder antispasmodic

### Indications and Dosages

- *To treat overactive urinary bladder with symptoms of frequency, urge incontinence, and urgency*

#### **TABLETS**

**Adults.** 5 mg daily; if tolerated well, increased to 10 mg daily.

***DOSAGE ADJUSTMENT*** For patients with severe renal impairment or moderate hepatic impairment or patients taking ketoconazole or other potent CYP3A4 inhibitors, dosage limited to 5 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	3-8 hr	Unknown

## Mechanism of Action

Antagonizes the effect of acetylcholine on muscarinic receptors in detrusor muscle, decreasing the muscle spasms that cause inappropriate bladder emptying. This action increases bladder capacity and volume, which relieves the sensation of frequency and urgency and enhances bladder control.

## Contraindications

Gastric retention, hypersensitivity to solifenacin or its components, uncontrolled angle-closure glaucoma, urine retention

## Interactions

### DRUGS

*CYP3A4 inducers:* Possibly decreased concentration of solifenacin and its effectiveness

*ketoconazole, other potent CYP3A4 inhibitors:* Increased serum concentrations of solifenacin and increased risk of adverse effects

## Adverse Reactions

**CNS:** Confusion, delirium, depression, dizziness, fatigue, hallucinations, headache, somnolence

**CV:** **Atrial fibrillation**, hypertension, palpitations, peripheral edema, **prolonged QT interval**, tachycardia, **torsades de pointes**

**EENT:** Blurred vision, distortion of sense of taste, dry eyes or mouth, glaucoma, nasal dryness, pharyngitis

**GI:** Abdominal pain, anorexia, constipation, elevated liver enzymes gastroesophageal reflux disease, ileus, indigestion, nausea, vomiting

**GU:** Renal impairment, UTI, urinary retention

**MS:** Muscle weakness

**RESP:** **Airway obstruction from angioedema**, cough, dysphonia

**SKIN:** Dry skin, **erythema multiforme**, **exfoliative dermatitis**, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, flu-like symptoms, **hyperkalemia**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Use cautiously in patients with intestinal atony, myasthenia gravis, or ulcerative colitis because solifenacin may decrease GI motility; in patients with significant bladder outflow obstruction because solifenacin may cause urine retention; in patients with hepatic impairment because solifenacin is metabolized in the liver; and in patients with renal impairment because solifenacin excretion may be impaired.
- Monitor patient closely, even after first dose, for hypersensitivity reactions. Although uncommon, anaphylactic reactions and angioedema have occurred with solifenacin therapy. Be prepared to manage these life-threatening reactions and expect drug to be discontinued if they occur.
- Monitor patient for signs of anticholinergic CNS adverse reactions, especially after treatment is begun or dosage increased.
- Monitor elderly patients, especially those age 75 and over, for adverse reactions because they're at increased risk for solifenacin-induced adverse reactions.

## **PATIENT TEACHING**

- Instruct patient to take solifenacin with a full glass of water and to swallow the tablet whole.
- Caution patient to avoid exertion in a warm or hot environment because sweating may be delayed, which could increase body temperature and increase risk of heatstroke.
- Advise patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Inform patient that alcohol may cause drowsiness, and urge patient to limit or avoid alcoholic beverages while taking solifenacin.

**solriamfetol hydrochloride**

**Sunosi**

## **Class and Category**

*Pharmacologic class: Dopamine and norepinephrine reuptake inhibitor*

*Therapeutic class: Analeptic*

*Controlled substance schedule: IV*

## Indications and Dosages

- *To improve wakefulness in patients with excessive daytime sleepiness associated with narcolepsy*

### **TABLETS**

**Adults.** 75 mg once daily, increased after at least 3 days to 150 mg once daily, if needed. *Maximum:* 150 mg daily.

- *To improve wakefulness in patients with excessive daytime sleepiness associated with obstructive sleep apnea*

### **TABLETS**

**Adults.** 37.5 mg once daily, then doubled at intervals of at least 3 days to maximum dose, as needed. *Maximum:* 150 mg daily.

***DOSAGE ADJUSTMENT*** For patients with an estimated glomerular filtration rate between 30 and 59 ml/min, initial dose reduced or kept at 37.5 mg once daily, with dose increased to a maximum of 75 mg once daily after at least 7 days. For patients with an estimated glomerular filtration rate between 15 and 29 ml/min, dosage reduced or kept at 37.5 mg once daily with no titration.

## Mechanism of Action

Unknown but thought to be related to its activity as a dopamine and norepinephrine reuptake inhibitor.

# Contraindications

Hypersensitivity to solriamfetol or its components, use within 14 days of MAO inhibitors

# Interactions

## DRUGS

*dopaminergic drugs:* Possibly altered pharmacodynamic effects

*drugs that increase blood pressure:* Increased risk of hypertension

*MAO inhibitors:* Increased risk of hypertensive crisis

# Adverse Reactions

**CNS:** Agitation, anxiety, bruxism, disturbances in attention, dizziness, feeling jittery, headache, insomnia, irritability, panic attack, restlessness, thirst, tremor

**CV:** Chest discomfort or pain, hypertension, palpitations, tachycardia

**EENT:** Dry mouth

**GI:** Abdominal pain, anorexia, constipation, diarrhea, nausea, vomiting

**RESP:** Cough, dyspnea

**SKIN:** Excessive diaphoresis

**Other:** Weight loss

# Childbearing Considerations

## PREGNANCY

- Pregnancy exposure registry: 1-877-283-6220 or [www.SunosiPregnancyRegistry.com](http://www.SunosiPregnancyRegistry.com).

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, mother should monitor infant for agitation, anorexia, insomnia, and reduced weight gain.

## **Nursing Considerations**

- Obtain patient's blood pressure prior to beginning solriamfetol therapy; blood pressure must be adequately controlled before drug is given, as hypertension increases risk of adverse cardiovascular events, including cardiovascular death, CVA, or MI.
- Use solriamfetol cautiously in patients with risk factors for major adverse cardiovascular events, especially patients with known cardiovascular and cerebrovascular disease, preexisting hypertension, and patients with advanced age. Also, use caution if patient is taking other drugs that increase blood pressure and heart rate.
- Use solriamfetol cautiously in patients with bipolar disorders or psychosis. Be aware that patients with moderate or severe renal impairment may be at higher risk of psychiatric symptoms because of the prolonged half-life of the drug.
- Split 75-mg tablet in half when dosage calls for 37.5 mg.
- Monitor patient's blood pressure and heart rate throughout solriamfetol therapy. Notify prescriber if elevations occur. Expect new-onset hypertension or exacerbations of preexisting hypertension to be treated. Know that if patient experiences increases in blood pressure or heart rate that cannot be managed with a dosage reduction of drug or other appropriate measures, drug will likely be discontinued.
- Monitor patient for psychiatric symptoms such as anxiety, insomnia, and irritability that may occur with solriamfetol therapy.
- Monitor patient for possible emergence or exacerbation of psychiatric symptoms. If they occur, notify prescriber and expect dosage to be

reduced or drug discontinued.

## PATIENT TEACHING

- Tell patient taking a 37.5-mg dose to split a 75-mg tablet in half.
- Instruct patient to take solriamfetol upon awakening and to avoid taking drug within 9 hours of planned sleep because drug may interfere with sleep if taken too late in the day.
- Teach patient how to take a blood pressure and pulse rate. Provide guidelines for when to call prescriber if elevated. Also tell patient to seek emergency care if signs or symptoms of a heart attack or stroke are present.
- Inform patient that anxiety, insomnia, and irritability may occur with drug use. If troublesome, tell patient to discuss with prescriber.

## sotalol hydrochloride

**Betapace, Betapace AF, Sorine,  
Sotacor (CAN), Sotalol I.V.**

## Class and Category

*Pharmacologic class:* Nonselective beta blocker

*Therapeutic class:* Class III antiarrhythmic

## Indications and Dosages

➤ *To treat life-threatening ventricular arrhythmias*

## CAPSULES, TABLETS

**Adults.** *Initial:* 80 mg twice daily, increased, as needed, in increments of 80 mg every 3 days provided patient's QT interval is less than 500 msec. *Maintenance:* 160 to 320 mg daily in divided doses twice daily or three times a day.

*Maximum:* 640 mg daily.

**Children 2 years old and over:** *Initial:* 30 mg/m<sub>2</sub> every 8 hr; may be titrated up to 60 mg/m<sub>2</sub>/day allowing 36 hr between

dosage adjustments. *Maximum:* 60 mg/m<sub>2</sub>/day.

**Children under age 2 years.** Highly individualized.

## **I.V. INFUSION (SOTALOL I.V.)**

**Adults.** *Loading dose:* Highly individualized and dependent on the creatinine clearance and target oral dose. Loading dose administered over 1 hour. *Maintenance:* 75 mg when substituted for 80 mg oral dose; 112.5 mg when substituted for 120 mg oral dose; and 150 mg when substituted for 160 mg oral dose. All maintenance doses infused over 5 hr.

*Maximum:* 150mg daily.

➤ *To delay recurrence of atrial fibrillation and atrial flutter in patients currently in sinus rhythm*

## **CAPSULES, TABLETS**

**Adults.** *Initial:* 80 mg twice daily, increased every 3 days in 80 mg increments daily provided QTc interval is less than 500 msec. *Usual:* 120 mg twice daily.

*Children 2 years old and over:* *Initial:* 30 mg/m<sup>2</sup> every 8 hr; may be titrated up to 60 mg/m<sup>2</sup>/day allowing 36 hr between dosage adjustments. *Maximum:* 60 mg/m<sub>2</sub>/day.

**Children under 2 years of age.** Highly individualized.

## **I.V. INFUSION (SOTALOL I.V.)**

**Adults.** *Loading dose:* Highly individualized and dependent on the creatinine clearance and target oral dose. Loading dose administered over 1 hour. *Maintenance:* 75 mg when substituted for 80 mg oral dose; 112.5 mg when substituted for 120 mg oral dose; and 150 mg when substituted for 160 mg oral dose. All maintenance doses infused over 5 hr. *Maximum:* 150 mg twice daily.

**DOSAGE ADJUSTMENT** For adult patients treated for ventricular arrhythmias and with a creatinine clearance between 30 and 59 ml/min, oral dosage interval reduced to every 24 hours; if creatinine clearance is between 10 and 29 ml/min, oral dosage interval increased to 36 or 48 hours; and if creatinine clearance is less than 10 ml/min, dosage individualized. For adult patients treated for atrial fibrillation or flutter, with a creatinine clearance between 40 to 59 ml/min, dosing interval increased to every 24 hours.

Route	Onset	Peak	Duration
P.O.	Unknown	2–3 hr	Unknown

## Mechanism of Action

Combines class II and class III antiarrhythmic activity to increase sinus cycle length. This beta blocker decreases AV nodal conduction and increases AV nodal refractoriness. Suppression of SA node automaticity and AV node conductivity decreases atrial and ventricular ectopy.

## Contraindications

Acquired or congenital QT syndromes; bronchial asthma or related bronchospastic conditions; atrial fibrillation or flutter (if baseline QT interval exceeds 450 msec or creatinine clearance is less than 40 ml/min); cardiogenic

shock; decompensated, heart failure; hypersensitivity to sotalol or its components; second- or third-degree AV block, sick sinus syndrome, or sinus bradycardia without functioning pacemaker

## Interactions

### DRUGS

*antacids*: Altered sotalol effectiveness

*calcium channel*: Additive effects on atrioventricular conduction or ventricular function resulting in bradycardia and hypotension

*catecholamine-depleting agents such as guanethidine,*

*reserpine*: Possibly excessive reduction of resting sympathetic nervous tone resulting in marked bradycardia and/or hypotension causing syncope

*class I, II, and III antiarrhythmias*: Prolonged refractoriness possibly resulting in prolonged QT interval

*clonidine*: Increased risk of bradycardia; increased risk of rebound hypertension when clonidine discontinued

*digoxin*: Increased risk of bradycardia

*insulin, oral antidiabetic drugs*: Impaired glucose control, increased risk of hyperglycemia

## Adverse Reactions

**CNS**: Anxiety, depression, dizziness, drowsiness, fatigue, insomnia, lethargy, nervousness, weakness

**CV**: **AV conduction disorders, bradycardia, heart failure, hypotension**, peripheral vascular insufficiency

**EENT**: Nasal congestion

**ENDO**: Hyperglycemia, **hypoglycemia**

**GI**: Abdominal pain, constipation, diarrhea, nausea, vomiting

**GU:** Sexual dysfunction

**MS:** Muscle weakness

**RESP:** **Bronchospasm**, dyspnea, wheezing

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Expect to obtain baseline creatinine clearance and QT interval before starting sotalol and periodically throughout therapy, as ordered.
- Monitor apical and radial pulses, blood pressure, circulation in limbs, daily weight, fluid intake and output, and respiratory rate, before and during sotalol therapy.
- Know that if prescriber is stopping amiodarone, sotalol shouldn't be started until QT interval has returned to baseline because of possible adverse cardiac effects.
- Be aware that stopping sotalol abruptly may cause life-threatening reactions. For this reason, chronic beta blocker therapy such as sotalol is not routinely withheld prior to major surgery. However, be aware that the impaired ability of the heart to respond to reflex adrenergic stimuli may increase the risks of general anesthesia and surgical procedures.
- Monitor serum electrolyte levels because drug can increase risk of torsades de pointes in patients with electrolyte imbalances, especially hypokalemia or hypomagnesemia.

- Assess carefully if patient has diabetes mellitus or thyrotoxicosis because they may mask hypoglycemia and hyperthyroidism.

## PATIENT TEACHING

- Advise patient to notify prescriber immediately if he has difficulty breathing.
- Urge patient to consult prescriber before taking OTC drugs, especially cold remedies, which may decrease sotalol's effectiveness.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.

## spectinomycin hydrochloride

### Trobicin

## Class and Category

*Pharmacologic class:* Aminoglycoside

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat acute cervicitis, proctitis, and urethral gonorrhea caused by susceptible strains of Neisseria gonorrhoeae*

## I.M. INJECTION

**Adults.** 2 g as a single dose.

**DOSAGE ADJUSTMENT** For patients living in geographic area where antibiotic resistance is known to be prevalent, dosage increased to 4 g as a single dose given as two separate 2 g dose injections.

## Mechanism of Action

Binds to negatively charged sites on bacterial outer cell membrane, disrupting cell integrity, and binds to bacterial ribosomal subunits, inhibiting protein synthesis. Both actions lead to bacterial cell death.

## Contraindications

Hypersensitivity to spectinomycin or its components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Dizziness, insomnia

**GI:** Abdominal cramps, nausea, vomiting

**Other:** Injection-site pain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- To reconstitute spectinomycin, add 3.2 ml bacteriostatic water for injection (with benzyl alcohol) to each 2-g vial. Shake vial vigorously before withdrawing dose.
- Administer I.M. injection using a 20-gauge needle deep into large muscle mass, preferably upper outer quadrant of gluteal muscle. 4 g dose may be divided between two gluteal injection sites.

## PATIENT TEACHING

- Tell patient he'll be tested for syphilis at the start of treatment and 3 months later because spectinomycin treatment may delay or mask syphilis symptoms.
- Explain risk factors for sexually transmitted diseases, and teach correct condom use.
- Advise patient to encourage sexual partner to be tested for gonorrhea.
- Instruct patient to notify prescriber if signs and symptoms persist after a few days.

**spironolactone**

**Aldactone, Carospir**

## Class and Category

*Pharmacologic class: Potassium-sparing diuretic*  
*Therapeutic class: Diuretic*

## Indications and Dosages

- *To increase survival and to reduce need for hospitalization for heart failure when used in addition to standard therapy in patients with severe heart failure (NYHA class III-IV) and reduced ejection fraction*

### **TABLETS (ALDACTONE)**

**Adults with serum potassium of 5.0 mEq/l or less and an estimated glomerular filtration rate (eGFR) greater than 50 ml/min.** *Initial:* 25 mg once daily. Dosage increased to 50 mg once daily, as needed.

**Adults with an eGFR between 30 and 50 ml/min.** 25 mg every other day.

***DOSAGE ADJUSTMENT*** If patient does not tolerate 25 mg once daily, dosage reduced to 25 mg every other day.

### **ORAL SUSPENSION (CAROSPIR)**

**Adults with a serum potassium of 5.0 mEq/l or less and eGFR greater than 50 ml/min.** *Initial:* 20 mg (4 ml) once daily, increased to 37.5 mg (7.5 ml) once daily, if needed.

**Adults with an eGFR between 30 to 50 ml/min.** 10 mg (2 ml) once daily.

***DOSAGE ADJUSTMENT*** For heart failure patients who develop hyperkalemia while receiving a dose of 20 mg (4 ml) daily, dosage reduced to 20 mg (4 ml) every other day.

- *To treat hypertension*

## TABLETS (ALDACTONE)

**Adults.** *Initial:* 25 to 100 mg daily as a single dose or in divided doses for at least 2 wk; gradually adjusted every 2 wk, as needed, to control blood pressure. *Maximum:* 100 mg daily.

## ORAL SUSPENSION (CAROSPIR)

**Adults.** *Initial:* 20 mg (4 ml) to 75 mg (15 ml) daily as a single dose or in divided doses for at least 2 wk; gradually adjusted every 2 wk as needed if initial dose less than 75 mg (15 ml). *Maximum:* 75 mg (15 ml) daily.

➤ *To treat edema associated with hepatic cirrhosis*

## TABLETS (ALDACTONE)

**Hospitalized adults.** *Initial:* 100 mg daily as a single dose or in divided doses, for at least 5 days if given as the only agent for diuresis. *Usual:* 25 to 200 mg daily as a single dose or in divided doses.

## ORAL SUSPENSION (CAROSPIR)

**Hospitalized adults.** *Initial:* 75 mg (15 ml) daily as a single dose or in divided doses, for at least 5 days if given as the only agent for diuresis. Increased slowly to maximum dose, as needed. *Maximum:* 100 mg (20 ml) daily.

➤ *To treat primary hyperaldosteronism*

## TABLETS (ALDACTONE)

**Adults waiting for surgery.** 100 to 400 mg daily.

**Adults unable to have surgery.** Highly individualized with lowest effective dosage given.

---

Route

Onset

Peak

Duration

Route	Onset	Peak	Duration
P.O.*	Unknown	2–3 days	2–3 days

\* For diuretic effect; others unknown.

## Contraindications

Addison's disease, concomitant use of eplerenone, hyperkalemia, hypersensitivity to spironolactone or its components

## Interactions

### DRUGS

*ACE inhibitors, aldosterone blockers, angiotensin II antagonists, heparin and low molecular weight heparin, NSAIDs, other potassium-sparing diuretics, potassium-containing drugs, potassium supplements, trimethoprim:* Increased risk of severe hyperkalemia

*acetylsalicylic acid:* Possibly reduced effectiveness of spironolactone

*cholestyramine:* Increased risk of hyperkalemic metabolic acidosis

*digoxin:* Possibly increased half-life of digoxin

*lithium:* Possibly lithium toxicity

*NSAID:* Decreased antihypertensive effect of spironolactone

## Mechanism of Action

Normally, aldosterone attaches to receptors on the walls of distal convoluted tubule cells, causing sodium ( $\text{Na}^+$ ) and water ( $\text{H}_2\text{O}$ ) reabsorption in the blood, as

shown at left. Spironolactone competes with aldosterone for these receptors, thereby preventing sodium and water reabsorption and causing their excretion through the distal convoluted tubules, as shown below right. Increased urinary excretion of sodium and water reduces blood volume and blood pressure.

Description

## FOODS

*high potassium diet, low-salt milk, salt substitutes:*  
Increased risk of severe hyperkalemia

## Adverse Reactions

**CNS:** Ataxia, confusion, dizziness, drowsiness, **encephalopathy**, fatigue, fever, headache, lethargy, somnolence

**CV:** **Hypotension**, vasculitis

**EENT:** Increased intraocular pressure, nasal congestion, tinnitus, vision changes

**ENDO:** Breast or nipple pain, gynecomastia, hyperglycemia

**GI:** Abdominal cramping or pain, anorexia, constipation, diarrhea, flatulence, **gastric bleeding** or ulceration, gastritis, **mixed cholestatic/hepatocellular toxicity**, nausea, vomiting

**GU:** Amenorrhea, decreased libido, impotence, irregular menses, postmenopausal bleeding, **renal failure**, worsening renal function

**HEME:** **Agranulocytosis, aplastic anemia, leukopenia, neutropenia, thrombocytopenia**

**RESP:** Cough, dyspnea

**MS:** Arthralgia, back and leg pain, leg cramps, muscle weakness, myalgia

**SKIN:** Alopecia, erythematous or maculopapular cutaneous eruptions, pruritus, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, dehydration, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, **hyperkalemia**, hyperuricemia, **hypocalcemia**, **hypochloremic metabolic alkalosis**, **hypomagnesemia**, **hyponatremia**

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm affecting sex differentiation of the male fetus.
- Drug should be avoided in pregnant women.

### LACTATION

- Drug is not present in breast milk but an active metabolite has been found in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Be aware that for patients who have trouble swallowing, pharmacist may crush spironolactone tablets, mix with flavored syrup, and dispense as a suspension. It's stable for 1 month when refrigerated.
- Do not interchange oral suspension for tablet form as the two formulations are not therapeutically equivalent. For patients requiring a dose greater than 100 mg, tablet form must be used.
- Expect to evaluate patient's serum potassium level 1 week after spironolactone therapy begins, after each dosage adjustment, monthly for the first 3 months, quarterly for 1 year, and then every 6 months thereafter or as ordered. Notify prescriber if level exceeds 5 mEq/L or patient's renal function deteriorates (serum creatinine level exceeding 4 mg/dl). If patient has severe heart failure, know that potassium supplementation should be discontinued and patient followed closely, because hyperkalemia may be fatal in such patients.
- Evaluate spironolactone's effectiveness by assessing blood pressure and presence and degree of edema.
- Monitor patients with renal impairment closely because risk of adverse reactions is greater in these patients, as well as the elderly, because spironolactone is substantially excreted by the kidneys. Also be aware that patients with impaired renal function are at higher risk for hyperkalemia.

**WARNING** Monitor patient with hepatic impairment, especially if patient has ascites and cirrhosis, because spironolactone can cause sudden alterations in fluid and electrolyte balance which may cause coma, impaired neurological function, or worsening hepatic encephalopathy. Be aware that patients with hepatic impairment accompanied by ascites and cirrhosis should be given spironolactone initially in a hospital setting.

## PATIENT TEACHING

- Instruct patient to take spironolactone with meals or milk.

- Tell patient who can't swallow tablets that drug is available as a suspension.
- Teach patient who takes spironolactone for hypertension how to measure his blood pressure. Urge him to monitor it regularly and report pressure greater than 140 mm Hg systolic or 90 mm Hg diastolic to prescriber.
- Caution patient that he may experience dizziness during spironolactone therapy if fluid balance is altered.
- Warn patient to avoid performing hazardous activities, such as driving, until adverse effects of drug are known.
- Instruct patient to inform prescriber of any new condition or new drug therapy, including over-the-counter medications so that prescriber can evaluate if the patient is at increased risk for hyperkalemia.
- Advise women to report suspected or known pregnancy to prescriber.
- Alert patient that there is a potential risk to the fetus if it is male because of the drug's anti-androgenic properties. Encourage her to use effective contraceptive measures throughout spironolactone therapy.

# stavudine

## Zerit

## Class and Category

*Pharmacologic class:* Nucleoside analogue

*Therapeutic class:* Antiretroviral

## Indications and Dosages

- *As adjunct to treat human immunodeficiency virus type 1 (HIV-1) infection*

**CAPSULES, ORAL SOLUTION**

**Adults and children weighing at least 60 kg (132 lb).**  
40 mg every 12 hr.

**Adults weighing less than 60 kg (132 lb) and children weighing at least 30 kg (66 lb) to less than 60 kg (132 lb).** 30 mg every 12 hr.

**Neonates at least 14 days old and children weighing less than 30 kg (66 lb).** 1 mg/kg every 12 hr.

**Neonates from birth to 13 days old.** 0.5 mg/kg every 12 hr.

**DOSAGE ADJUSTMENT** For adults with a creatinine clearance between 26 and 50 ml/min and weighing at least 60 kg (132 lb), dosage reduced to 20 mg every 12 hr and if weighing less than 60 kg (132 lb), dosage reduced to 15 mg every 12 hr. For adults with a creatinine clearance between 10 and 25 ml/min and weighing at least 60 kg (132 lb), dosage reduced and interval increased to 20 mg every 24 hr and for adults weighing less than 60 kg (132 lb), dosage reduced and interval increased to 15 mg every 24 hr. For patients on hemodialysis, dosage and interval are the same as for patients with a creatinine clearance of 10 to 25 ml/min, but dosage is administered after the completion of hemodialysis on dialysis days and at the same time of day on nondialysis days. There are no specific recommendations for children with renal insufficiency.

## **Mechanism of Action**

Inhibits the activity of HIV-1 reverse transcriptase by competing with the natural substrate thymidine triphosphate to cause DNA chain termination following its incorporation into viral DNA. It also inhibits selective cellular DNA polymerases to markedly reduce the synthesis of mitochondrial DNA.

# Contraindications

Concomitant therapy with didanosine, hypersensitivity to stavudine or its components

# Interactions

## DRUGS

*doxorubicin, ribavirin*: Possibly interfere with action of stavudine and its effectiveness

*hydroxyurea*: Increased risk for toxicities such as hepatotoxicity, pancreatitis, and severe peripheral neuropathy

*zidovudine*: Interferes with action of stavudine, potentially rendering it ineffective

## ACTIVITIES

*alcohol use*: Increased risk of liver damage or pancreatitis

# Adverse Reactions

**CNS**: Chills, fever, headache, insomnia, motor weakness (severe), peripheral neurologic symptoms including neuropathy

**ENDO**: Cushingoid appearance, diabetes mellitus, fat redistribution, hyperglycemia

**GI**: Abdominal pain, anorexia, diarrhea, elevated liver and pancreatic enzymes, **hepatic failure or toxicity**, **hepatomegaly with steatosis** that may become severe, hyperlactatemia (symptomatic), nausea, **pancreatitis**, vomiting

**HEME**: Anemia, **leukopenia**, macrocytosis, **neutropenia**, **thrombocytopenia**

**MS:** Myalgia

**SKIN:** Rash

**Other:** Immune reconstitution syndrome, hypersensitivity reactions, lactic acidosis, lipoatrophy, lipodystrophy

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Be aware that the drug in combination with didanosine is contraindicated in pregnant women because of an increased risk of lactic acidosis.

### LACTATION

- Drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Know that when stavudine is used with other agents with similar toxicities, the incidence of these toxicities may be higher than when stavudine is used alone. For example, use with didanosine may increase risk of hepatotoxicity, pancreatitis, and severe peripheral neuropathy. Know that the combination of didanosine and stavudine should be used with caution during pregnancy and is recommended only if the potential benefit clearly outweighs the potential risk.
- Know that extreme caution is needed when administering stavudine with patients with known risk factors for liver disease, because of increased risk of liver abnormalities that may become severe or even fatal. Be aware

that the combination of stavudine along with didanosine and hydroxyurea should be avoided, because of increased risk of hepatotoxicity and hepatic failure that may result in death. Monitor liver enzymes and patient for evidence of worsening liver dysfunction. If present, notify prescriber and expect drug therapy to be interrupted or discontinued.

**WARNING** Monitor patient closely for signs and symptoms of symptomatic hyperlactatemia or lactic acidosis syndrome which may be severe, such as gastrointestinal (abdominal pain, nausea, vomiting, or unexplained weight loss), generalized fatigue, neurologic symptoms such as motor weakness, and respiratory symptoms (dyspnea, tachypnea). Although being of female gender, having prolonged nucleoside exposure, or obesity increases risk, patients without these risk factors have also developed lactic acidosis and severe hepatomegaly with steatosis. Notify prescriber immediately if patient becomes symptomatic or has laboratory values suggestive of lactic acidosis, pronounced hepatotoxicity, or symptomatic hyperlactatemia. Know that hepatomegaly and steatosis may occur without marked transaminase elevations. If confirmed, expect drug to be discontinued.

- Monitor patient for peripheral neuropathy. Know that motor weakness may mimic Guillain-Barré syndrome, including respiratory failure requiring drug to be discontinued immediately even though symptoms may continue or worsen after drug therapy has been stopped. Be aware that peripheral sensory neuropathy (numbness, pain, or tingling in feet or hands) most often occurs in patients with advanced HIV-1 disease or history of peripheral neuropathy, or in patients receiving other drugs that have been associated with neuropathy, including didanosine.
- Monitor patient for changes in appearance related to fat redistribution, such as the development of breast enlargement, central obesity, cushingoid appearance, dorsocervical fat enlargement (buffalo hump), and facial and peripheral wasting caused by antiretroviral therapy such as stavudine.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including stavudine. The

inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

## PATIENT TEACHING

- Advise patient to avoid missing doses of stavudine. If she misses a dose, she should take it as soon as she remembers, but should not double the next dose or take more than prescribed.

**WARNING** Inform patient about severe liver disease that may occur with stavudine. Tell her to report signs and symptoms of liver disease, such as acholic stools, anorexia, fatigue, malaise, nausea, tenderness over liver area, or yellowing of skin or whites of the eyes, and to seek immediate medical attention.

**WARNING** Instruct patient on early symptoms of lactic acidosis or symptomatic hyperlactatemia, such as abdominal discomfort, dyspnea, fatigue, nausea, motor weakness, unexplained weight loss, or vomiting. If present, tell patient to seek immediate medical attention, as drug may have to be discontinued.

- Warn patient to be alert for signs and symptoms of peripheral neuropathy such as numbness, pain, or tingling in feet or hands. If present, she should notify prescriber.
- Inform patient that stavudine therapy may cause changes in her body appearance because of fat redistribution. Prepare her for the possibility of developing breast enlargement, central obesity, dorsocervical fat enlargement (buffalo hump), facial wasting, and peripheral wasting.
- Instruct patient to report any persistent, severe, or unusual signs and symptoms. Inform patient taking other drugs in combination with stavudine with similar adverse effects that the incidence of adverse reactions may be higher than when stavudine is used alone.
- Alert mothers that breastfeeding is not recommended during stavudine therapy.

- Tell patients with diabetes to monitor their blood glucose closely, as stavudine may increase blood glucose levels. Also tell patient taking oral solution that it contains 50 mg of sucrose (sugar) per ml.
- Warn patient to avoid alcohol intake while taking drug, because the combination may increase the risk of liver damage or pancreatitis.

## streptomycin sulfate

### Class and Category

*Pharmacologic class:* Aminoglycoside

*Therapeutic class:* Antibiotic

### Indications and Dosages

- *To treat gram-negative bacillary bacteremia, meningal infections, pneumonia, systemic infections, and UTI*

#### I.M. INJECTION

**Adults.** 1 to 2 g daily in divided doses every 6 to 12 hr.

*Maximum:* 2 g daily.

**Children.** 20 to 40 mg/kg daily in divided doses every 6 to 12 hr.

**Neonates.** 7.5 mg every 12 hr.

- *As adjunct to treat endocarditis caused by Streptococcus viridans or E. faecalis*

#### I.M. INJECTION

**Adults.** 1 g twice daily for 1 wk (*S. viridans*) or 2 wk (*E. faecalis*) with penicillin. Then, 500 mg twice daily for 1 wk (*S. viridans*) or 4 wk (*E. faecalis*).

**Children.** 20 to 30 mg/kg in 2 divided doses in conjunction with other anti-infectives for 4 wk; 6 wk if used with vancomycin

**DOSAGE ADJUSTMENT** For patients over 60 years of age being treated for streptococcal endocarditis, dosage reduced to 500 mg twice daily for entire 2 week period.

➤ *As adjunct to treat active tuberculosis*

## **I.M. INJECTION**

**Adults.** 15 mg/kg daily. *Maximum:* 1 g daily. Alternatively, 25 to 30 mg/kg twice weekly. *Maximum:* 1.5 g daily.

**Children.** 20 to 40 mg/kg daily. *Maximum:* 1 g daily. Alternatively, 25 to 30 mg/kg twice weekly. *Maximum:* 1.5 g daily.

➤ *To treat plague caused by Yersinia pestis*

## **I.M. INJECTION**

**Adults.** 2 g daily in 2 or 3 equally divided doses for at least 10 to 14 days.

**Children.** 30 mg/kg daily (up to 2 g) in divided doses twice daily or three times a day for 10 to 14 days.

➤ *To treat tularemia caused by Francisella tularensis*

## **I.M. INJECTION**

**Adults.** 1 to 2 g daily in divided doses for 10 to 14 days.

**Children.** 15 mg/kg twice daily (up to 2 g daily) for 10 to 14 days.

➤ *As adjunct to treat brucellosis caused by Brucella melitensis*

## **I.M. INJECTION**

**Adults.** 1 g (or 15 mg/kg) once daily for initial 2 to 3 wk of oral doxycycline given for 4 to 6 wk.

**Children.** 20 to 40 mg/kg daily in divided doses every 6 to 12 hr in conjunction with other anti-infectives.

**DOSAGE ADJUSTMENT** If creatinine clearance is 50 to 80 ml/min dosage reduced to 7.5 mg/kg I.M. every 24 hr; if 10 to 49 ml/min 7.5 mg/kg I.M. every 24 to 72 hr; if less than 10 ml/min, 7.5 mg/kg I.M. every 72 to 96 hr.

## **Mechanism of Action**

Binds to negatively charged sites on the bacteria's outer cell membrane, disrupting cell integrity. Streptomycin also binds to bacterial ribosomal subunits and inhibits protein synthesis. Both actions lead to bacterial cell death.

## **Incompatibilities**

Don't mix streptomycin in same solution or administer through same I.V. line as other antibiotics.

## **Contraindications**

Hypersensitivity to streptomycin, other aminoglycosides, or their components

## **Interactions**

### **DRUGS**

*capreomycin*: Possible increased risk of nephrotoxicity or ototoxicity

*carbapenems (imipenem)*: Possible additive or synergistic antibacterial effects against some gram-positive bacteria  
*cephalosporins*: Increased incidence of nephrotoxicity; possible inactivation of streptomycin  
*colistimethate/colistin, cyclosporine, other aminoglycosides, polymyxin B, vancomycin*: Possible increased risk of nephrotoxicity and/or neurotoxicity  
*diuretics*: Increased risk of ototoxicity  
*neuromuscular blocking agents including general anesthetics (decamethonium, rocuronium, succinylcholine, tubocurarine)*: Possible increase in neuromuscular blockade and respiratory paralysis  
*NSAIDs*: Possible increased serum streptomycin concentrations  
*penicillins*: Additive or synergistic antibacterial effects; possible inactivation of streptomycin

## Adverse Reactions

**CNS**: Clumsiness, dizziness, **neurotoxicity**, paresthesia, peripheral neuropathy, **seizures**, unsteadiness, vertigo

**EENT**: Hearing loss, sensation of fullness in ears, tinnitus, vision loss

**GI**: Anorexia, nausea, thirst, vomiting

**GU**: Decreased or increased urine output, **nephrotoxicity**

**MS**: Muscle twitching

**SKIN**: Erythema, pruritus, rash, urticaria

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm by causing congenital deafness.
- Drug should not be used during pregnancy.

## LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Use streptomycin cautiously in patients with renal impairment. In severely uremic patients, single dose can produce high blood level of drug for several days; cumulative effects may produce ototoxicity.
- Expect prescriber to order baseline renal function studies and to assess cranial nerve VIII function (responsible for hearing) at start of streptomycin therapy to allow for later comparisons.
- Monitor serum peak and trough levels, as ordered, to ensure adequate, but not toxic, drug level.
- Be aware that streptomycin should be given only by I.M. injection.
- To reconstitute streptomycin, add between 4.2 and 4.5 ml of sodium chloride for injection or sterile water for injection to each 1-g vial to provide a concentration of 200 mg/ml, or add between 3.2 and 3.5 ml of diluent to each 5-g vial to provide a concentration of 250 mg/ml. Alternatively, add 6.5 ml of diluent to each 5-g vial to provide a concentration of 500 mg/ml.
- Don't give more than 500 mg/ml.
- Rotate injection sites to prevent sterile abscess formation.

## PATIENT TEACHING

- Advise patient to refrigerate streptomycin solution at 2° to 8°C (36° to 46°F).
  - Inform patient that treatment for tuberculosis lasts at least 1 year.
  - Urge patient to notify prescriber if he has fullness or ringing in ears, hearing loss, or vertigo.
-

# sucralfate

## Carafate

### Class and Category

*Pharmacologic class:* GI protectant

*Therapeutic class:* Antiulcer

### Indications and Dosages

- *To prevent reoccurrence of duodenal ulcer*

#### **TABLETS**

**Adults and adolescents.** 1 g twice daily.

- *To treat active duodenal ulcer*

#### **ORAL SUSPENSION, TABLETS**

**Adults.** 1 g four times a day 1 hr before meals and at bedtime for 4 to 8 wk, possibly less.

### Mechanism of Action

May react with hydrochloric acid in the stomach to form a complex that buffers acid. The complex adheres electrostatically to proteins on the ulcer's surface and creates a protective barrier at the ulcer site. Sucralfate also inhibits back-diffusion of hydrogen ions and adsorbs bile acids and pepsin, actions that promote healing of an existing duodenal ulcer and prevent reoccurring ulcer formation.

# Interactions

## DRUGS

*cimetidine, ciprofloxacin, digoxin, fluoroquinolone antibiotics, ketoconazole, l-thyroxine, phenytoin, quinidine, tetracycline, theophylline*: Decreased bioavailability of these drugs

## Adverse Reactions

**CNS:** Dizziness, drowsiness, headache, insomnia, light-headedness, vertigo

**EENT:** Dry mouth

**ENDO:** Hyperglycemia

**GI:** Constipation, diarrhea, indigestion, nausea, vomiting

**MS:** Back pain

**RESP:** **Bronchospasm**, dyspnea

**SKIN:** Pruritus, rash, urticaria

**OTHER:** **Anaphylaxis, angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use sucralfate cautiously in patients with chronic renal failure because of increased risk of aluminum toxicity.
- Administer drug to patient when he has an empty stomach.
- Monitor diabetic patient's blood glucose level closely because sucralfate may cause hyperglycemia significant enough to require an adjustment of antidiabetic drug therapy prescribed.

## PATIENT TEACHING

- Instruct patient to take sucralfate on an empty stomach at least 1 hour before meals and at bedtime.
- Advise patient not to take antacids within 30 minutes of sucralfate.
- Caution patient to check with prescriber before taking another drug within 2 hours of sucralfate.

**sucroferric oxyhydroxide**

**Velphoro**

## Class and Category

*Pharmacologic class:* Polynuclear iron(III) oxyhydroxide

*Therapeutic class:* Phosphate binder

## Indications and Dosages

- *To control serum phosphorus levels in patients with chronic kidney disease on dialysis*

## **CHEWABLE TABLETS**

**Adults.** *Initial:* 500 mg three times daily with meals, increasing or decreasing dosage in 500-mg increments weekly, as needed. *Maintenance:* 1,500 to 2,000 mg daily. *Maximum:* 3,000 mg daily.

## **Mechanism of Action**

Phosphate binding takes place by ligand exchange between hydroxyl groups and/or water in sucroferic oxyhydroxide and phosphate in the diet. The bound phosphate is eliminated in feces. Both calcium phosphorus product levels and serum phosphorus levels are reduced as a consequence of the reduced dietary phosphate absorption.

## **Contraindications**

Hypersensitivity to sucroferic oxyhydroxide or its components

## **Interactions**

### **DRUGS**

*acetylsalicylic acid, cephalexin, doxycycline, levothyroxine:* Absorption of these drugs may be affected

## **Adverse Reactions**

**EENT:** Abnormal drug distaste, tooth discoloration

**GI:** Dark-colored feces, diarrhea, nausea

**SKIN:** Rash

## **Childbearing Considerations**

## **PREGNANCY**

- Drug is not absorbed systemically and not expected to result in fetal exposure.

## **LACTATION**

- Drug is not absorbed systemically and not expected to result in fetal exposure.

## **Nursing Considerations**

- Give sucroferric oxyhydroxide with meals and administer all other oral drugs prescribed for the patient at a different time because absorption of the other drugs may be affected.
- Monitor patient's serum phosphorus levels regularly, as ordered, to determine drug effectiveness and need for dosage adjustments.
- Monitor patients who have a history of hemochromatosis or other diseases characterized by iron accumulation, patients who develop peritonitis during peritoneal dialysis, and patients with significant gastric or hepatic disorders or following major gastrointestinal surgery, because sucroferric oxyhydroxide effects on these conditions are not known.

## **Patient Teaching**

- Instruct patient to take sucroferric oxyhydroxide with meals.
  - Tell patient tablets must be chewed and not swallowed whole. Tell him the tablets may be crushed to aid chewing and swallowing them.
  - Inform patient that drug may cause discolored (black) stool but this effect is harmless. Inform patient that drug may also stain teeth.
  - Instruct patient to take any concomitant drug therapy at least 2 hours before sucroferric oxyhydroxide.
  - Tell patient to report any rash to prescriber.
-

# sufentanil

**Dsuvia**

## Class, Category, and Schedule

*Pharmacologic class:* Opioid agonist

*Therapeutic class:* Opioid analgesic

*Controlled substance schedule:* II

## Indications and Dosages

- *To relieve acute pain severe enough to require an opioid analgesic and for which alternative treatments are inadequate in a medically supervised healthcare setting, such as emergency departments, hospitals, and surgical centers*

### SUBLINGUAL TABLETS

**Adults.** 30 mcg, as needed, with a minimum of 1 hr between doses. *Maximum:* 360 mcg or 12 tablets in 24 hr, and not for use for more than 72 hr.

## Mechanism of Action

Binds to and activates selective mu-opioid receptors found throughout the central nervous system to produce pain relief.

## Contraindications

Acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment, gastrointestinal obstruction including paralytic ileus, hypersensitivity to sufentanil or its components, significant respiratory depression

## Interactions

### DRUGS

*5-HT<sub>3</sub> inhibitors (used to treat psychiatric disorders), linezolid, methylene blue (intravenous), selective serotonin reuptake inhibitors, serotonin and norepinephrine reuptake inhibitors, tricyclic antidepressants, triptans:* Increased risk of serotonin syndrome

*anticholinergic drugs:* Possibly increased risk of urinary retention and/or severe constipation, which may lead to paralytic ileus

*benzodiazepines and other CNS depressants:* Increased risk of serious adverse reactions such as coma, hypotension, profound sedation, and severe respiratory depression

*CYP3A4 inducers such as carbamazepine, phenytoin, rifampin:* Decreased plasma concentration of sufentanil, resulting in decreased efficacy or possible withdrawal symptoms in patients who have developed physical dependence to sufentanil

*CYP3A4 inhibitors such as azole-antifungal agents (ketoconazole), macrolide antibiotics (erythromycin), and protease inhibitors (ritonavir):* Increased plasma concentration of sufentanil, resulting in increased or prolonged effects

*diuretics:* Reduced efficacy of diuretics

*MAO inhibitors:* Increased risk of serotonin syndrome; increased risk of opioid toxicity

*mixed agonist/antagonist or partial agonist opioid analgesics such as buprenorphine, butorphanol, nalbuphine, pentazocine:* Possibly reduced analgesic effect of sufentanil and possible precipitation of withdrawal symptoms

*muscle relaxants:* Possibly enhanced neuromuscular blocking action of skeletal muscle relaxants; increased degree of respiratory depression

## **ACTIVITIES**

*alcohol use:* Increased risk of serious adverse reactions such as coma, hypotension, profound sedation, and severe respiratory depression

## **Adverse Reactions**

**CNS:** Agitation, anxiety, confusion, disorientation, dizziness, euphoric mood, hallucination, headache, hemiparesis, insomnia, lethargy, memory impairment, mental status changes, **seizures**, **serotonin syndrome**, somnolence, syncope

**CV:** **Bradycardia**, **electrocardiogram abnormalities**, hypertension, **hypotension (severe)**, orthostatic hypotension, tachycardia

**EENT:** Oral hypoesthesia

**ENDO:** **Adrenal insufficiency**

**GI:** Abdominal distention or pain, belching, constipation, diarrhea, dyspepsia, elevated liver enzymes, flatulence, gastritis, nausea, postoperative ileus, vomiting

**GU:** Decreased urine output, oliguria, **renal failure**, urinary hesitation or retention

**MS:** Muscle spasms

**RESP:** **Apnea**, **atelectasis**, **bradypnea**, **decreased oxygen saturation and respiratory rate**,

**hypoventilation, hypoxia, life-threatening respiratory depression, respiratory distress or failure**

**SKIN:** Diaphoresis, flushing, pruritus, rash

**Other:** **Anaphylaxis**, physiological and physical dependence

## **Childbearing Considerations**

### **PREGNANCY**

- Drug may cause fetal harm.
- Prolonged use of drug during pregnancy can result in Neonatal Opioid Withdrawal Syndrome, which may be life-threatening if not recognized and treated.
- Avoid prolonged use during pregnancy. Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LABOR & DELIVERY**

- Drug is not recommended for use in pregnant women immediately before or during labor. Opioids may alter length of time of labor.
- Opioids cross the placenta and may produce respiratory depression and psycho-physiologic effects in the neonate. Monitor neonate closely for signs of excess sedation and respiratory depression.
- An opioid antagonist, such as naloxone, must be available at the time of delivery in the event it is needed to reverse opioid-induced respiratory depression in the neonate.

### **LACTATION**

- Drug is present in breast milk.
- Breastfeeding should not be undertaken during drug therapy.

### **REPRODUCTION**

- Chronic use of opioids may reduce fertility in females and males.

## Nursing Considerations

- Be aware that excessive use of sufentanil may lead to abuse, addiction, misuse, overdose, and possibly death. Know that sufentanil is available only through a restricted Risk Evaluation and Mitigation Strategy (REMS) program. Monitor patient's intake of drug closely. Alert prescriber if patient has a history of dependence on other opioids.
- Know that drug is only administered in a healthcare setting and never self-administered by patient.
- Use extreme caution when administering sufentanil to patients with significant chronic obstructive pulmonary disease or cor pulmonale, and to patients having a substantially decreased respiratory reserve, hypercapnia, hypoxia, or preexisting respiratory depression, especially when initiating or titrating therapy. These patients may develop respiratory depression, even with usual therapeutic doses, because sufentanil may decrease patient's respiratory drive to the point of apnea.
- Know that sufentanil may cause sleep-related disorders including central sleep apnea and sleep-related hypoxemia increasing the risk in a dose-dependent fashion. If patient develops central sleep apnea, know that sufentanil dose may need to be decreased.
- Use sufentanil cautiously in cachectic, debilitated, or elderly patients, especially when initiating and titrating therapy, as these patients are at increased risk for adverse effects, especially respiratory depression.
- Put on gloves and tear open the notched pouch only when ready to administer sufentanil. Be aware that the pouch contains one clear plastic single-dose applicator (SDA) that houses a single blue-colored tablet in the tip. Remove the white lock from the green pusher by squeezing the sides together and detaching from pusher. To avoid accidentally ejecting the tablet, avoid touching the green pusher before placing the SDA in patient's mouth for administration. To administer, tell patient to open mouth and touch the tongue to the roof of the mouth, if possible. Rest the SDA lightly on patient's lips or lower teeth. Place the SDA tip under the tongue and aim at the floor of patient's mouth or sublingual space. Avoid direct mucosal contact with the SDA tip. Gently depress the green pusher to deliver the tablet to patient's sublingual space. Visually confirm tablet placement. Be aware that if tablet is not in patient's mouth, it must be retrieved and disposed of according to institutional CII waste procedures. Discard the used SDA in biohazard waste container after administration.

**WARNING** Monitor patient for respiratory depression that could become life-threatening quickly, especially when drug is initiated or if patient is accidentally exposed to drug. However, know that respiratory depression may occur at any time during sufentanil use and may occur even when used as recommended. If patient develops respiratory depression, expect to give naloxone. Watch for seizures, because naloxone may increase this risk. Take seizure precautions.

- Be aware that sufentanil may increase the frequency of seizures in patients with seizure disorders and may increase risk of seizures in the presence of other conditions associated with seizures. Monitor patient closely.
- Be aware that opioids like sufentanil should not be given to women during pregnancy, while in labor, or when breastfeeding, as newborn or infant may experience neonatal opioid withdrawal syndrome (NOWS). This syndrome may exhibit as excessive or high-pitched crying, poor feeding, rapid breathing, or trembling. If not recognized and treated appropriately, it can become life-threatening.
- Monitor patients closely who may be susceptible to the intracranial effects of carbon dioxide retention from respiratory depression caused by sufentanil therapy, such as patients with head injuries or those who have a preexisting elevation in intracranial pressure.

**WARNING** Know that many drugs may interact with opioids like sufentanil to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with coordination, or vomiting. Notify prescriber at once, because serotonin syndrome may be life-threatening. Be prepared to discontinue drug, if possible and ordered, and provide supportive care.

- Monitor effectiveness of sufentanil in relieving pain; consult prescriber as needed.

- Assess patient for constipation and provide a high-fiber diet and adequate fluid intake, if not contraindicated, because constipation can become severe.
- Monitor patient for evidence of physical dependence or abuse. Know that addiction can occur not only in those who obtain drug illicitly but also in patients who are appropriately prescribed drug at recommended doses. Be aware that excessive use of sufentanil may lead to abuse, addiction, misuse, overdose, and possibly death.
- Notify prescriber if serious adverse reactions occur with sufentanil therapy and expect dosage to be reduced.
- Monitor patient's vital signs closely. Know that in addition to respiratory depression, sufentanil may cause severe hypotension, especially in patients whose blood pressure is already compromised by a depleted blood volume or after concurrent administration of drugs that decrease blood pressure. Also be aware that the drug may cause bradycardia in some patients.
- Be aware that concomitant use with CYP3A4 inhibitors or discontinuation of CYP3A inducers can result in a fatal overdose of sufentanil.
- Monitor patient for adrenal insufficiency. Although rare, it can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, or weakness. Notify prescriber if adrenal insufficiency is suspected and expect diagnostic testing to be done. If diagnosis is confirmed, expect to administer corticosteroids and discontinue sufentanil.
- Monitor patient for decreased bowel motility in postoperative patients receiving sufentanil, as drug may obscure the development of acute abdominal conditions.

**WARNING** Be aware that sufentanil should only be used concomitantly with benzodiazepine therapy in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of sufentanil to be limited. Monitor patient closely for signs and symptoms of a decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

## PATIENT TEACHING

- Instruct patient to allow sufentanil tablet to dissolve under the tongue and not to chew or swallow the tablet. Also advise patient not to drink or eat and to minimize talking for 10 minutes after each dose of the drug.
- Warn patient of possibility of addiction even when taken as prescribed.
- Alert patient that respiratory depression may occur with sufentanil use, especially when drug is first given, and to report any breathing difficulties immediately.
- Warn patient to keep sufentanil away from the reach of children, as accidental consumption of even one tablet can cause significant respiratory depression and death.
- Caution patient to avoid having alcohol or other drugs brought to him in the healthcare setting because ingesting alcohol, including medications containing alcohol, increases the risk of overdose, respiratory depression, and death, as does taking other types of depressants, including benzodiazepines, together with sufentanil therapy.
- Advise women of childbearing age to notify prescriber if pregnancy is known or suspected, because a fetus exposed to sufentanil while in utero may require treatment for neonatal opioid withdrawal syndrome (NOWS) when born. Also advise women not to breastfeed while taking sufentanil.
- Instruct patient to rise slowly from a lying or sitting position and to lie or sit down if he experiences light-headedness. If effect is frequent or severe, tell him to notify prescriber.
- Urge patient to consume plenty of fluids and high-fiber foods, if not contraindicated, to prevent constipation.

## sulfadiazine

### Class and Category

*Pharmacologic class:* Sulfonamide

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *As adjunct to treat chloroquine-resistant malaria, Haemophilus influenzae acute otitis media (with penicillin) or meningitis (with streptomycin), or toxoplasmosis encephalitis (with pyrimethamine); to prevent or treat meningococcal meningitis; to treat chancroid, inclusive conjunctivitis, nocardiosis, or trachoma; to treat urinary tract infections caused by Enterobacter species, Escherichia coli, Klebsiella species, Proteus mirabilis, P. vulgaris, and Staphylococcus aureus after failure with other sulfonamides*

### **TABLETS**

**Adults.** *Initial:* 2 to 4 g. *Maintenance:* 2 to 4 g daily, divided into 3 to 6 doses.

**Infants age 2 months and over and children.** *Initial:* 75 mg/kg. *Maintenance:* 150 mg/kg daily divided into 4 to 6 doses. *Maximum:* 6 g daily.

- *To prevent rheumatic fever*

### **TABLETS**

**Children weighing more than 30 kg (66 lb).** 1 g daily.

**Children weighing less than 30 kg (66 lb).** 500 mg daily.

## Mechanism of Action

Inhibits para-aminobenzoic acid, a bacterial enzyme responsible for synthesizing folic acid, which susceptible bacteria require for growth. By inactivating bacteria, sulfadiazine prevents or alleviates infection.

# Contraindications

Breastfeeding; hypersensitivity to sulfadiazine, its components, or other chemically related drugs, such as sulfonamides; infants under the age of two months except as adjunctive treatment for congenital toxoplasmosis; pregnancy at term

# Interactions

## DRUGS

*indomethacin, probenecid, salicylates:* Increased concentration of sulfadiazine

*methotexate, oral anticoagulants, sulfonylurea*

*hypoglycemic agents, thiazide diuretics, uricosuric agents:* Increased effects of these drugs increasing risk of adverse reactions

# Adverse Reactions

**CNS:** Dizziness, fatigue, fever, headache, lethargy, weakness

**EENT:** Pharyngitis

**GI:** Anorexia, diarrhea, dysphagia, jaundice, nausea, vomiting

**GU:** Crystalluria

**HEME:** Agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, thrombocytopenia, unusual bleeding or bruising

**MS:** Arthralgia, myalgia

**SKIN:** Blisters, erythema, pallor, photosensitivity, pruritus, rash

**Other:** Drug-induced fever

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Use sulfadiazine cautiously in patients with blood dyscrasias or megaloblastic anemia from folate deficiency because drug may cause blood dyscrasias; in those with G6PD deficiency because hemolysis may occur; in those with hepatic or renal impairment because of increased risk of toxicity; and in those with porphyria because drug may precipitate an acute attack.
- Obtain blood sample for CBC and body tissue or fluid specimen for culture and sensitivity tests, as ordered, before giving drug. Expect first dose to be given before results are available.

**WARNING** Monitor patient for drug-induced fever, which may develop 7 to 10 days after starting sulfadiazine therapy. Signs and symptoms may include abdominal pain, anorexia, ataxia, depression, diarrhea, headache, insomnia, nausea, peripheral neuropathy, tinnitus, and vomiting.

- Monitor fluid intake and output during therapy. Altered fluid balance may increase risk of crystalluria.

- Monitor patient's blood glucose level, and assess for signs and symptoms of hypoglycemia in patients who take an oral antidiabetic drug. Be prepared to respond if hypoglycemia develops.

## PATIENT TEACHING

- Instruct patient to take sulfadiazine exactly as prescribed and to complete the full course, even if he feels better.
- Advise patient to take drug with a full glass of water and to drink plenty of fluids during therapy.
- Urge patient to notify prescriber if urine turns reddish brown; this may indicate crystalluria.
- Inform patient about possible dizziness, and urge him to avoid potentially hazardous activities until drug's CNS effects are known.
- Advise patient to avoid prolonged exposure to sunlight and to wear sunscreen and protective clothing when outdoors.
- Urge patient who takes oral contraceptives to use an additional method of birth control during therapy.
- Advise patient who takes an oral antidiabetic drug to check his blood glucose level frequently because of the increased risk of hypoglycemia during therapy.

## sulfasalazine

**Azulfidine, Azulfidine EN-Tabs,  
Salazopyrin (CAN), Salazopyrin EN-  
Tabs (CAN)**

## Class and Category

*Pharmacologic class:* Salicylate-sulfonamide

*Therapeutic class: Anti-inflammatory*

## Indications and Dosages

- *To treat mild-to-moderate ulcerative colitis; as adjunct to treat severe ulcerative colitis; to prolong remission period between acute attacks of ulcerative colitis*

### DELAYED-RELEASE TABLETS, TABLETS

**Adults and adolescents.** *Initial:* 500 to 1,000 mg every 6 to 8 hr. *Maintenance:* 500 mg every 6 hr.

**Children age 6 and over.** *Initial:* 40 to 60 mg/kg daily divided into 3 to 6 doses. *Maintenance:* 30 mg/kg daily divided into 4 doses.

- *To treat rheumatoid arthritis in patients who have not responded to salicylates or other NSAIDs*

### DELAYED-RELEASE TABLETS

**Adults.** *Initial:* 500 to 1,000 mg daily during wk 1, increased by 500 mg daily every wk, as needed, up to 2,000 mg daily in divided doses. If no response after 12 wk, increased to 3,000 mg daily. *Maintenance:* 1,000 mg every 12 hr. *Maximum:* 3,000 mg daily.

- *To treat juvenile rheumatoid arthritis in patients who have not responded to salicylates or other NSAIDs*

### DELAYED-RELEASE TABLETS

**Children ages 6 and over.** 30 to 50 mg/kg daily in divided doses twice daily. *Maximum:* 2 g daily.

***DOSAGE ADJUSTMENT*** For patients with ulcerative colitis, initial dosage may be reduced if GI intolerance occurs. For adult patients with rheumatoid arthritis as a means to reduce possible GI intolerance, initial dosage may be

reduced to 0.5 to 1 g daily and then increased weekly as needed. For children with juvenile rheumatoid arthritis as a means to reduce possible GI intolerance, initial dosage may be reduced to one-quarter to one-third of expected maintenance dose and then gradually increased weekly to reach maintenance dose.

## **Mechanism of Action**

As a prodrug of sulfapyridine and 5-aminosalicylic acid (mesalamine), delivers more sulfapyridine and mesalamine to the colon than either metabolite could provide alone. Sulfapyridine provides antibacterial action along the intestinal wall; mesalamine inhibits cyclooxygenase, thereby decreasing the production of arachidonic acid metabolites and reducing colonic inflammation. It also reduces joint inflammation locally caused by rheumatoid arthritis.

## **Contraindications**

Hypersensitivity to salicylates, sulfasalazine or its metabolites, sulfonamides, or their components; intestinal or urinary obstruction; porphyria

## **Interactions**

### **DRUGS**

*digoxin*: Possibly inhibited absorption and decreased blood level of digoxin

*folic acid (vitamin B<sub>9</sub>)*: Decreased folic acid absorption

*methotrexate*: Increased incidence of gastrointestinal adverse reactions, especially nausea

# Adverse Reactions

**CNS:** Ataxia, chills, depression, fatigue, fever, **Guillain-Barré syndrome**, headache, insomnia, **meningitis**, peripheral neuropathy, **seizures**, vertigo, weakness

**CV:** **Myocarditis**, **pericarditis**, vasculitis

**EENT:** Hearing loss, orange-yellow tears, oropharyngeal pain, pharyngitis, tinnitus

**GI:** Abdominal pain, anorexia, **cirrhosis**, diarrhea, elevated liver enzymes, **hepatitis**, **hepatotoxicity**, indigestion, jaundice, nausea, **pancreatitis**, ulcerative colitis exacerbation, vomiting

**GU:** Crystalluria, decreased ejaculatory volume, male infertility, **nephritis**, nephrolithiasis, **nephrotic syndrome**, orange-yellow urine, **toxic nephrosis**

**HEME:** **Agranulocytosis**, **aplastic anemia**, **hemolytic anemia**, **hematophagic histiocytosis**, **leukopenia**, **neutropenia**, **thrombocytopenia**, **unusual bleeding** or bruising

**MS:** Arthralgia, **rhabdomyolysis**

**RESP:** **Cyanosis**, **eosinophilic infiltration**, **idiopathic pulmonary fibrosis**, **lymphocytic interstitial pneumonitis**, pleuritis pneumonia

**SKIN:** Alopecia, **erythema multiforme**, **exfoliative dermatitis**, photosensitivity, pruritus, purpura, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **drug rash with eosinophilia and systemic symptoms (DRESS)**, folate deficiency, infections (serious), lupus erythematosus-like syndrome, mononucleosis-like syndrome, **sepsis**, serum sickness syndrome

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm. However, drug does pass the placental barrier increasing risk of kernicterus in the neonate.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Infants less than 2 months of age should not be breastfed because of risk of kernicterus. Patient should check with prescriber before breastfeeding older infants.
- Be aware that studies are mixed regarding drug causing bloody stools and/or diarrhea in breastfed infants.

## Nursing Considerations

- Use sulfasalazine cautiously in patients with a history of recurring or chronic infections because drug may predispose patient to infections. Monitor patients for new infections throughout therapy. If present, notify prescriber.
- Monitor BUN and serum creatinine levels, CBC, and liver enzymes, before and periodically during prolonged sulfasalazine therapy.
- Be aware that sulfasalazine doses over 4 g or a blood level over 50 mcg/ml increases the risk of adverse and toxic reactions.
- Monitor fluid intake and output and urine color, consistency, and pH. Acidic urine may require alkalization to prevent crystalluria.
- Be aware that measurements, by liquid chromatography, of urinary normetanephrine may cause a false-positive test result.

**WARNING** Monitor patient, especially during the first month of sulfasalazine therapy, for hypersensitivity reactions that may become life-threatening. At first sign of mucosal lesions, rash, or any other sign of

hypersensitivity, stop sulfasalazine therapy and notify prescriber.

## PATIENT TEACHING

- Instruct patient to take sulfasalazine with an antacid, meals, or milk to decrease GI distress, and to swallow tablets whole.
- Advise patient to prevent crystalluria by taking drug with a full glass of water and drinking at least 64 oz of fluid per day.
- Instruct patient and family to administer drug around the clock.
- Inform patient that symptom relief may take 2 to 5 days for ulcerative colitis and 4 to 12 weeks for rheumatoid arthritis.
- Alert patient that drug may turn skin and urine orange-yellow.
- Advise contact lens wearer to consider wearing glasses during therapy because drug can permanently stain contact lenses yellow.
- Instruct patient to avoid prolonged sun exposure and to wear protective clothing and sunscreen when outdoors.
- Advise patient to brush with a soft-bristled toothbrush and to use dental floss and toothpicks gently because leukopenic and thrombocytopenic drug effects increase risk of gingival bleeding and infection.
- Urge patient to return for laboratory tests and follow-up visits to monitor drug's effect.
- Instruct patient to report fever; jaundice; paleness; skin abnormalities such as skin blistering, discoloration, rash or hives; or sore throat. These may be signs of serious adverse effects. Explain that prescriber may order tests to determine their cause and that drug may be discontinued until test results are known.
- Instruct mothers who are breastfeeding to stop taking sulfasalazine or stop breastfeeding immediately if their infant develops bloody stools or diarrhea, and to notify prescriber.

**sulindac**

# Class and Category

*Pharmacologic class:* NSAID

*Therapeutic class:* Analgesic, anti-inflammatory

## Indications and Dosages

- *To decrease pain and inflammation in ankylosing spondylitis, osteoarthritis, and rheumatoid arthritis*

### TABLETS

**Adults.** *Initial:* 150 mg twice daily, adjusted based on patient's response. *Maximum:* 200 mg twice daily.

- *To relieve symptoms of acute gouty arthritis, acute subacromial bursitis, and supraspinatus tendinitis*

### TABLETS

**Adults.** 200 mg twice daily for 7 days for acute gouty arthritis and 7 to 14 days for bursitis and tendinitis; decreased to lowest effective dosage after satisfactory response occurs.

*Maximum:* 400 mg daily.

Route	Onset	Peak	Duration
P.O.	In 1 wk*	2–3 wk*	Unknown

\* For antirheumatic effects; unknown for antigout or anti-inflammatory effects.

## Mechanism of Action

May block the activity of cyclooxygenase, an enzyme needed to synthesize prostaglandins, which mediate the inflammatory response that cause local vasodilation, pain,

and swelling. By blocking cyclooxygenase and inhibiting prostaglandins, this NSAID reduces inflammatory symptoms and pain.

## Contraindications

Asthma, urticaria, or allergic-type reactions induced by aspirin or other NSAIDs; hypersensitivity to sulindac, other NSAIDs, and their components; in setting of coronary artery bypass graft (CABG) surgery

## Interactions

### DRUGS

*angiotensin-converting enzyme (ACE) inhibitors, angiotensin II antagonists:* Decreased antihypertensive effect of these drugs; increased risk of renal impairment in patients with already compromised renal function

*cyclosporine:* Increased cyclosporine-induced toxicity

*diflunisal:* Decreased plasma sulindac levels, decreasing effectiveness

*dimethyl sulfoxide (DMSO):* Decreased sulindac effectiveness, possibly peripheral neuropathy

*diuretics:* Possibly decreased diuretic effects

*lithium:* Possibly increased blood level and toxic effects of lithium

*methotrexate:* Decreased methotrexate excretion, possibly leading to toxicity

*other NSAIDs, warfarin:* Increased risk of gastrointestinal toxicity including GI bleeding

*platelet aggregation inhibitors:* Increased risk of bleeding, additive effects of these drugs

*probenecid:* Increased blood level and adverse and toxic effects of sulindac

## ACTIVITIES

*alcohol use:* Increased risk of adverse GI effects, including GI bleeding

## Adverse Reactions

**CNS:** Aseptic meningitis, chills, CVA, drowsiness, fever, headache, malaise, nervousness, transient ischemic attack

**CV:** Deep vein thrombosis, edema, heart failure, hypertension, MI, palpitations, peripheral edema, vasculitis

**EENT:** Tinnitus

**ENDO:** Hypoglycemia

**GI:** Abdominal cramps or pain, anorexia, constipation, diarrhea, esophageal irritation, flatulence, gastritis, GI bleeding or ulceration, hepatic failure, hepatitis, hepatotoxicity, indigestion, jaundice, nausea, perforation of intestines or stomach, vomiting

**GU:** Acute renal failure, decreased urine output, interstitial nephritis, nephrotic syndrome, polyuria, proteinuria

**HEME:** Agranulocytosis, aplastic anemia, leukopenia, pancytopenia

**RESP:** Bronchospasm, dyspnea, pulmonary edema, wheezing

**SKIN:** Diaphoresis, erythema multiforme, exfoliative dermatitis, maculopapular rash, pruritus, purpura, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis, angioedema, hypersensitivity reactions

## Childbearing Considerations

## PREGNANCY

- Drug increases risk of premature closure of the fetal ductus arterisus if given during the third trimester of pregnancy.
- Drug should be avoided in pregnant women starting at 30 weeks of gestation and onward.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Use sulindac with extreme caution in patients with a history of GI bleeding or ulcer disease because NSAIDs such as sulindac increase risk of GI bleeding and ulceration. Expect to use sulindac for the shortest time possible in these patients.
- Be aware that serious GI tract bleeding, perforation, and ulceration may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber at once.
- Use sulindac cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

**WARNING** Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

- Be aware that if patient has systemic lupus erythematosus and mixed connective tissue disease, monitor him closely because sulindac increases the risk of aseptic meningitis.

**WARNING** Know that if patient has bone marrow suppression or is receiving antineoplastic drug therapy, monitor

laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of sulindac may mask signs and symptoms, such as fever and pain.

- Monitor patient closely, especially if patient is elderly or taking sulindac long term, watch for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver enzymes because, in rare cases, elevated levels may progress to severe hepatic reactions, including fatal hepatitis, hepatic failure, and liver necrosis.
- Watch BUN and serum creatinine levels in elderly patients; those with heart failure, hepatic dysfunction, or impaired renal function; and those taking ACE inhibitors or diuretics; because drug may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit because drug may worsen anemia.
- Assess patient's skin routinely for rash or other signs of hypersensitivity reaction because sulindac and other NSAIDs may cause serious skin reactions without warning, even in patients with no history of NSAID hypersensitivity. Stop drug at first sign of reaction, and notify prescriber.

**WARNING** Monitor patient for adventitious breath sounds and dyspnea; sulindac may cause fluid retention, which may precipitate heart failure in susceptible patients.

- Expect patient to undergo audiometric examinations before and periodically during prolonged therapy, as ordered.

**WARNING** Monitor patient for evidence of hypersensitivity syndrome, which could become life-threatening. Report multiple occurring and multiorgan adverse reactions to prescriber and expect drug to be discontinued. Be prepared to provide emergency supportive care, as ordered.

## **PATIENT TEACHING**

- Instruct patient to take sulindac exactly as prescribed. Explain that higher doses don't increase effectiveness and may increase risk of adverse reactions.
- Advise patient to crush tablet and mix with food, if needed, to aid in swallowing.
- Instruct patient to take drug with or immediately after meals to decrease GI distress, to take with a full glass of water, and to remain upright for 20 to 30 minutes after administration to prevent drug from lodging in esophagus and causing esophageal irritation.
- Urge patient to notify prescriber immediately of chills, fever, rash, or sweating, which may indicate hypersensitivity.
- Advise patient to consult prescriber before using acetaminophen, alcohol, aspirin, other NSAIDs, or any OTC drugs during sulindac therapy.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Explain the need for periodic laboratory tests and physical examinations during prolonged therapy to monitor drug effectiveness.
- Inform patient that sulindac may increase the risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, slurring of speech, or weakness.
- Tell patient that sulindac also may increase the risk of serious adverse GI reactions; stress the need to seek immediate medical attention for such signs and symptoms as abdominal or epigastric pain, black or tarry stools, indigestion, or vomiting blood or material that looks like coffee grounds.
- Alert patient to the possibility of rare but serious hypersensitivity reactions. Urge him to seek immediate medical attention for blisters, fever, itching, rash, or other indications of hypersensitivity.

**sumatriptan**

**Imitrex**

**sumatriptan succinate**

# Imitrex, Sumavel Dose Pro, Zembrace SymTouch

## Class and Category

*Pharmacologic class:* Serotonin 5-HT<sub>1</sub>-receptor agonist

*Therapeutic class:* Antimigraine

## Indications and Dosages

➤ *To relieve acute migraine attacks, with or without aura*

### **TABLETS (IMITREX)**

**Adults.** 25, 50, or 100 mg as a single dose as soon as possible after onset of symptoms, repeated after at least 2 hr, as needed. *Maximum:* 200 mg daily.

***DOSAGE ADJUSTMENT*** For patients with mild-to-moderate hepatic dysfunction, 50 mg is maximum single dose.

### **SUBCUTANEOUS INJECTION (ZEMBRACE SYMTOUCH)**

**Adults.** *Initial:* 3 mg, repeated after 1 hr, as needed. *Maximum:* 4 (3-mg) injections/24 hr with dosages separated by at least 1 hr.

### **SUBCUTANEOUS INJECTION (IMITREX, SUMAVEL DOSE PRO)**

**Adults.** *Initial:* 1 to 6 mg (Imitrex) or 4 or 6 mg (Sumavel Dose Pro) depending on severity of headache, repeated after at least 1 hr, as needed. *Maximum:* 12 mg in 24 hr with doses separated by at least 1 hr.

## NASAL SPRAY (IMITREX)

**Adults.** 5 mg and 20 mg given as a single spray in 1 nostril or 10 mg given as a single 5-mg spray in each nostril. One additional dose may be taken if migraine not resolved or another attack occurs after at least 2 hr. *Maximum:* 40 mg daily.

➤ *To relieve cluster headaches*

## SUBCUTANEOUS INJECTION (IMITREX, SUMAVEL DOSE PRO)

**Adults.** *Initial:* 6 mg, repeated after 1 or 2 hr, as needed. *Maximum:* 2 (6-mg) injections/24 hr with dosages separated by at least 1 hr.

Route	Onset	Peak	Duration
P.O.	In 30 min	2-4 hr	Up to 24 hr
SubQ	In 10 min	1-2 hr	Up to 24 hr
Nasal	In 15 min	Unknown	Up to 24 hr

## Mechanism of Action

May stimulate 5-HT<sub>1</sub> receptors, causing selective vasoconstriction of dilated and inflamed cranial blood vessels in carotid circulation, thus decreasing carotid arterial blood flow and relieving acute migraines and cluster headaches.

## Contraindications

History of CVA, basilar or hemiplegic migraine, or transient ischemic attack; hypersensitivity to sumatriptan or its components; ischemic bowel or coronary artery disease; peripheral vascular disease; recent use (within 24 hr) of

ergotamine-containing medication, ergot-type medication (such as dihydroergotamine or methysergide), or another 5-hydroxytryptamine<sub>1</sub> (5-HT<sub>1</sub>) agonist; severe hepatic impairment; Wolff-Parkinson-White syndrome or arrhythmias associated with other cardiac accessory conduction pathway disorders; uncontrolled hypertension; use of a MAO inhibitor within 14 days

## Interactions

### DRUGS

*antidepressants, lithium:* Increased risk of serious adverse effects

*ergotamine-containing drugs:* Possibly additive or prolonged vasoconstrictive effects including serotonin syndrome

*fluoxetine, fluvoxamine, paroxetine, sertraline:* Possibly hyper-reflexia, incoordination, and weakness

*MAO inhibitors:* Risk of decreased sumatriptan clearance, increased risk of serious adverse effects

*other triptans:* Additive vasospastic effects; increased risk of serotonin syndrome

*selective serotonin reuptake inhibitors, serotonin*

*norepinephrine reuptake inhibitors, tricyclic*

*antidepressants:* Increased risk of serotonin syndrome

## Adverse Reactions

**CNS:** Anxiety, atypical sensations, dizziness, drowsiness, fatigue, fever, headache, malaise, sedation, **serotonin syndrome, seizures**, vertigo, weakness

**CV:** **Arrhythmias**; chest heaviness, pain, pressure, or tightness; **coronary artery vasospasm; ECG changes**;

hypertension; **hypotension**; palpitations; peripheral vascular ischemia

**EENT:** Abnormal vision, blindness or partial vision loss, jaw or mouth discomfort, nasal burning (P.O., subcutaneous), nasal irritation (nasal), nose or throat discomfort, photophobia (P.O., subcutaneous), taste perversion (nasal), tongue numbness or soreness

**GI:** Abdominal discomfort, **bloody diarrhea, colonic ischemia**, dysphagia

**MS:** Jaw discomfort, muscle cramps, myalgia, neck pain or stiffness

**SKIN:** Diaphoresis, erythema, flushing, pallor, photosensitivity (P.O., subcutaneous), pruritus, rash, urticaria

**Other:** **Anaphylaxis; angioedema**; injection-site burning, erythema, hemorrhage, induration, irritation, pain, paresthesia, pruritis, swelling, and urticaria

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk following subcutaneous administration.
- Recommended that breastfeeding should be avoided for 12 hours after mother takes drug regardless of form taken.

## Nursing Considerations

- Be aware that sumatriptan shouldn't be given to elderly patients because they're more likely to have coronary artery disease (CAD) and more pronounced blood pressure increases.
- Assess patient for arrhythmias, chest pain, or other signs of heart disease and monitor blood pressure in patients with CAD before and for at least 1 hour after sumatriptan administration.
- Don't give sumatriptan within 24 hours of another 5-HT<sub>1</sub>-receptor agonist, such as naratriptan, rizatriptan, or zolmitriptan with the exception of a single dose of another sumatriptan product, provided the doses are separated by at least 1 to 2 hours depending on brand used. Don't give an ergotamine-containing or ergot-type drug within 24 hours of sumatriptan therapy. Doing so increases risk of serious adverse interactions and effects.
- After nasal spray administration, rinse tip of bottle with hot water (don't suction water into bottle) and dry with a clean tissue. Replace cap after cleaning.
- Inspect injection solution for discoloration and particles before administering. Discard solution if you detect these changes. Be aware that the needle shield of the prefilled syringe contains dry natural rubber, a latex derivative, that may cause allergic reactions in latex-sensitive persons.
- Be aware that parenteral form of drug shouldn't be administered I.V. because this may precipitate coronary artery vasospasm. Administer only as a subcutaneous injection.
- To use nasal powder, remove the clear device cap from the reusable delivery device, then remove a disposable nosepiece from its foil pouch and click the nosepiece into the device body. Then fully press and promptly release the white piercing button on the device body to pierce the capsule inside the nosepiece. The white piercing button should only be pressed once and released prior to administration to each nostril. Insert the nosepiece into the nostril so that it makes a tight seal. Keeping the nosepiece in the nose, rotate the device to place the mouthpiece into the mouth. Have patient blow forcefully through the mouthpiece to deliver the powder into the nasal cavity. A rattling noise may occur; this indicates that patient has blown forcefully. Once administered, have patient remove and discard the nosepiece. Repeat the procedure using a second 11-mg nosepiece into the other nostril.

**WARNING** Monitor patient closely for hypersensitivity reactions, including anaphylaxis and angioedema which may be life-threatening. If present, notify prescriber

immediately and expect to provide emergency supportive care according to institution emergency protocols.

- Know that for patients with seizure disorder, seizure precautions should be instituted according to facility policy because sumatriptan may lower seizure threshold.

**WARNING** Monitor patient closely for serotonin syndrome exhibited by agitation, coma, diarrhea, hyperreflexia, hyperthermia, incoordination, labile blood pressure, nausea, tachycardia, or vomiting. Notify prescriber immediately because serotonin syndrome may be life-threatening and provide supportive care.

## PATIENT TEACHING

- Advise patient to use sumatriptan as soon as possible after the onset of migraine symptoms.
- Urge patient to contact prescriber and avoid taking sumatriptan if headache symptoms aren't typical.
- Remind patient not to exceed prescribed daily dosage. Inform him that overuse of the drug for 10 or more days per month may lead to exacerbation of headache and may require detoxification. If his use of the drug increases, advise him to notify his prescriber.
- Advise patient to swallow tablets whole and drink fluids to disguise unpleasant taste.
- Show patient suitable sites for subcutaneous injection, and teach him how to load, administer, and discard autoinjector or how to use subcutaneous needle. Tell patient to alert prescriber if he is allergic to latex, as the needle cap of the prefilled syringe is made of a latex derivative. Or, explain how to administer drug using needle-free drug delivery system, Sumavel DosePro. (Snap off plastic tip, flip back lever into active position, and press end of device to the skin of abdomen or thigh.)
- Instruct patient not to exceed maximum doses and not to take a second dose if first dose doesn't provide significant relief.
- Inform patient that he may experience burning, pain, and redness for 10 to 30 minutes after subcutaneous injection. Suggest that he apply ice to

relieve pain and redness.

- Teach patient prescribed the nasal powder or nasal spray forms how to use correctly.
- Advise patient never to share the medication with another person even if they have the same symptoms, as cross-contamination and severe adverse reactions could occur.
- Encourage patient to lie down in a dark, quiet room after taking drug to help relieve migraine.
- Instruct patient to seek emergency care for chest, jaw, or neck tightness after drug use because drug may cause coronary artery vasospasm; subsequent doses may require ECG monitoring.
- Urge patient to report palpitations or rash to prescriber.
- Advise patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Alert patient with seizure disorder that drug may lower seizure threshold.
- Encourage yearly ophthalmologic examinations for patients who require prolonged drug therapy.
- Advise women of childbearing age to notify prescriber if pregnancy occurs.
- Inform woman who is breastfeeding that she should avoid breastfeeding for 12 hours after treatment with sumatriptan to minimize infant exposure to the drug.
- Urge patient to inform all prescribers of sumatriptan therapy because of potentially dangerous drug interactions.

**suvorexant**

**Belsomra**

## **Class, Category, and Schedule**

*Pharmacologic class:* Orexin receptor antagonist

*Therapeutic class: Hypnotic*  
*Controlled substance schedule: IV*

## Indications and Dosages

- *To treat insomnia characterized by difficulties with sleep onset and/or sleep maintenance*

### **TABLETS**

**Adults.** 10 mg once per night within 30 minutes of bedtime and with at least 7 hours remaining for sleep; increased, as needed, to 20 mg once daily. *Maximum:* 20 mg once daily at night.

***DOSAGE ADJUSTMENT*** For patients taking moderate CYP3A inhibitors, dosage reduced to 5 mg once per night, with maximum dosage not exceeding 10 mg once per night. For patients taking CNS depressants concurrently, dosage may have to be decreased.

## Mechanism of Action

Antagonism of orexin receptors blocks the binding of wake-promoting neuropeptides orexin A and orexin B to produce sleep.

## Contraindications

Hypersensitivity to suvorexant and its components, narcolepsy

## Interactions

### **DRUGS**

*CNS depressants:* Additive CNS and respiratory depression; increased risk of abnormal behavior and thinking

*CYP3A inducers:* Decreased effectiveness of suvorexant

*CYP3A inhibitors:* Increased effect of suvorexant and incidence of adverse reactions

*digoxin:* Increased serum digoxin levels

## **ACTIVITIES**

*alcohol use:* Additive CNS depression; increased risk of abnormal behavior and thinking

## **Adverse Reactions**

**CNS:** Abnormal dreams, amnesia, anxiety, cataplexy-like behaviors (mild), dizziness, hallucinations, headache, impaired daytime wakefulness, leg weakness (temporarily), psychomotor hyperactivity, sleep paralysis (temporarily), somnolence, **suicidal ideation**, worsening of depression

**CV:** Palpitations, tachycardia

**EENT:** Dry mouth

**GI:** Diarrhea

**RESP:** Cough, upper respiratory tract infection

**Other:** Physical and psychological dependence

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding takes place, mother should monitor infant for excessive sedation.

## **Nursing Considerations**

- Use suvorexant with extreme caution in patients with a history of alcohol or drug abuse because of risk of addiction.
- Use suvorexant cautiously in debilitated or elderly patients and those with depression or impaired respiratory function.
- Monitor obese patients and women closely for adverse effects because these patients are at increased risk. Be aware that there is a dosage relationship to development of adverse reactions in general.
- Monitor respiratory status, especially in patients with respiratory compromise, who are at increased risk for respiratory depression.
- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.

## **PATIENT TEACHING**

- Tell patient to take drug 30 minutes before bedtime on an empty stomach with at least 7 hours remaining for sleep time.
- Caution patient to avoid potentially hazardous activities after taking suvorexant; drug's intended effect is to decrease alertness. Tell patient that CNS depressant effects may persist in some patients for up to several days after the drug is discontinued.
- Advise patient that drug may cause abnormal behaviors during sleep that extend into daytime, causing wakefulness impairment. Such behaviors may include driving a car, eating, talking on the phone, or having sex without any recall of the event. If family members notice any such behavior or patient sees evidence of such behavior upon awakening, drug should be withheld and prescriber notified.
- Advise patient to avoid alcohol while taking suvorexant.

- Tell patient to notify prescriber if insomnia worsens or new signs or symptoms occur.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.

# T

## tacrolimus

**Astagraf XL, Envarsus XR, Hecoria, Prograf**

### Class and Category

*Pharmacologic class:* Calcineurin inhibitor

*Therapeutic class:* Immunosuppressant

*Pregnancy category:* C

### Indications and Dosages

- *To prevent organ rejection in patients undergoing allogeneic heart, kidney, or liver transplantation*

### **CAPSULES (HECORIA, PROGRAF), ORAL SUSPENSION**

**Adults having kidney transplantation in combination with azathioprine.** 0.2 mg/kg/day given in two equally divided doses every 12 hr beginning with first dose begun between 6 and 24 hr post-transplant but only after renal function has recovered (serum creatinine level of 4 mg/dl or less).

**Adults having kidney transplantation in combination with MMF/IL-2 receptor antagonist therapy.** 0.1

mg/kg/day given in two equally divided doses every 12 hr beginning with first dose begun between 6 and 24 hr post-transplant but only after renal function has recovered (serum creatinine level of 4 mg/dl or less).

**Children having kidney transplantation.** 0.3 mg/kg/day given in two equally divided doses every 12 hr.

**Adults having liver transplantation.** 0.10 to 0.15 mg/kg/day given in two equally divided doses every 12 hr. Administer first dose 6 hr after transplantation.

**Children having liver transplantation.** 0.15 to 0.20 mg/kg/day (capsules) or 0.2 mg/kg/day (oral suspension) given in two equally divided doses every 12 hr. Administer first dose 6 hr after transplantation.

**Adults having heart transplantation.** 0.075 mg/kg/day given in two equally divided doses every 12 hr. Administer first dose 6 hr after transplantation.

**Children having heart transplantation.** 0.3 mg/kg/day (0.1 mg/kg/day if cell-depleting induction treatment is administered) given in two equally divided doses every 12 hr.

## **I.V. INFUSION (PROGRAF)**

**Adults having kidney or liver transplantation.** 0.03 to 0.05 mg/kg/day as a continuous infusion beginning no sooner than 6 hr after transplantation.

**Adults having heart transplantation.** 0.01 mg/kg/day as a continuous infusion beginning no sooner than 6 hr after transplantation.

**Children having liver transplantation.** 0.03 to 0.05 mg/kg/day as a continuous infusion beginning no sooner than 6 hr after transplantation.

**DOSAGE ADJUSTMENT** For patients with hepatic or renal impairment, dosage kept at lower end of range with possible need for further reduction. Black patients may need higher doses after kidney transplantation to attain

comparable trough concentrations compared to Caucasian patients.

- *To prevent organ rejection in patients undergoing allogeneic kidney transplantation*

## **EXTENDED-RELEASE CAPSULES (ASTAGRAF XL)**

**Adults with basiliximab induction.** *Initial:* 0.15 to 0.2 mg/kg 1 hr before a meal or 2 hr after a meal and started prior to reperfusion or within 48 hr of completion of transplant procedure, but may be delayed until renal function has recovered. Dosage then adjusted to achieve target trough concentration range.

**Adults without basiliximab induction.** *Preoperatively:* 0.1 mg/kg as a single dose 1 hr before a meal or 2 hr after a meal within 12 hr prior to reperfusion. *Postoperatively:* 0.2 mg/kg as the second dose given 1 hr before a meal or 2 hr after a meal at least 4 hr after the preoperative dose and within 12 hr after reperfusion, then adjusted to achieve target trough concentration ranges.

***DOSAGE ADJUSTMENT FOR ASTAGRAF XL*** Black patients may need higher doses to attain comparable trough concentrations compared to Caucasian patients. For patients who have developed nephrotoxicity, dosage reduced. For patients with severe hepatic impairment, lower dosage may be required.

- *To prevent organ rejection in patients undergoing allogeneic kidney transplantation and are converting from a tacrolimus immediate-release product*

## **XR TABLETS (ENVARUS XR)**

**Adults.** *Initial:* 80% of total daily dose of immediate-release product given once daily on an empty stomach, then adjusted to achieve target whole blood trough concentration ranges of 4 to 11 ng/ml.

## Mechanism of Action

Inhibits T-lymphocyte activation, possibly by binding to an intracellular protein, FKBP-12. This binding results in formation of a complex of tacrolimus-FKBP-12, calcineurin, calcium, and calmodulin which inhibits phosphatase activity of calcineurin. This inhibition may prevent dephosphorylation and translocation of nuclear factor of activated T-cells, a nuclear component thought to initiate gene transcription for the formation of lymphokines. The result is inhibition of T-lymphocyte activation, which produces immunosuppression.

## Incompatibilities

Don't store diluted drug in PVC containers because of increased instability of tacrolimus and possible extraction of phthalates. Don't mix or coinfuse tacrolimus with solutions of pH 9 or greater, such as with acyclovir or ganciclovir, because of chemical instability of tacrolimus in alkaline media.

## Contraindications

Hypersensitivity to tacrolimus or its components, hypersensitivity to polyoxyl 60 hydrogenated castor oil (parenteral form)

## Interactions

### DRUGS

*aminoglycosides, amphotericin B, cisplatin, cyclosporine, CYP3A4 inhibitors, ganciclovir, nucleotide reverse*

*transcriptase inhibitors, other nephrotoxic drugs, protease inhibitors:* Increased risk of renal impairment  
*amiodarone, boceprevir, bromocriptine, chloramphenicol, cimetidine, cisapride, clarithromycin, clotrimazole, cyclosporine, danazol, diltiazem, erythromycin, ethinyl estradiol, fluconazole, ganciclovir, itraconazole, ketoconazole, lansoprazole, magnesium-aluminum-hydroxide, methylprednisolone, metoclopramide, nefazodone, nelfinavir, nicardipine, nifedipine, omeprazole, protease inhibitors, ritonavir, Schisandra sphenanthera extracts, telaprevir, troleandomycin, verapamil, voriconazole:* Possibly increased blood tacrolimus level  
*amiodarone, CYP3A4 inducers or inhibitors that have potential to prolong QT interval:* Possibly prolonged QT interval  
*carbamazepine, methylprednisolone, phenobarbital, phenytoin, prednisone, rifabutin, rifampin, St. John's wort:* Possibly decreased blood tacrolimus level  
*mycophenolic acid:* Possibly increased plasma mycophenolic acid level  
*sirolimus:* Increased risk of insulin-dependent post-transplant diabetes mellitus, renal dysfunction, and wound healing complications  
*vaccines (live or killed):* Possibly suppressed immune response and increased adverse effects of vaccine

## **FOODS**

*grapefruit, grapefruit juice:* Possibly increased blood tacrolimus trough levels in liver transplant patients  
*high-fat foods:* Decreased absorption of oral tacrolimus

## **ACTIVITIES**

*alcohol use (Astagraf XL, Envarsus XR):* Increased rate of release of tacrolimus

## Adverse Reactions

**CNS:** Asthenia, **coma**, **CVA**, delirium, dizziness, fever, headache, hemiparesis, insomnia, jittery feeling, **leukoencephalopathy**, mental changes, motor and sensory dysfunction, mutism, **neurotoxicity**, paresthesia, **posterior reversible encephalopathy syndrome**, **progressive multifocal leukoencephalopathy**, **seizures**, speech disorder, syncope, tremor

**CV:** **Atrial and ventricular arrhythmias**, **cardiac arrest**, chest pain, hypercholesterolemia, hyperlipemia, hypertension, hypertriglyceridemia, myocardial hypertrophy, **MI**, **myocardial ischemia**, **pericardial effusion**, peripheral edema, **QT-interval prolongation**, **torsades de pointes**, **venous thrombosis**

**EENT:** Blindness, cortical blindness, deafness, hearing loss, photophobia

**ENDO:** Cushingoid features, diabetes mellitus, hot flashes, hyperglycemia

**GI:** Abdominal pain, anorexia, ascites, bile duct stenosis, colitis, constipation, diarrhea, dyspepsia, enterocolitis, gastric ulcer, gastroenteritis, gastroesophageal reflux disease, **GI perforation**, **hepatic impairment or toxicity**, impaired gastric emptying, nausea, **pancreatitis**, **veno-occlusive liver disease**, vomiting

**GU:** BK virus nephropathy, elevated creatinine and BUN levels, hemorrhagic cystitis, **hemolytic-uremic syndrome**, micturition abnormality, **nephrotoxicity**, oliguria, **renal failure**, renal impairment, UTI

**HEME:** **Agranulocytosis**, anemia, **disseminated intravascular coagulation (DIC)**, **hemolytic anemia**,

leukocytosis, **leukopenia**, **neutropenia**, **pancytopenia**, **pure red cell aplasia**, **thrombocytopenia**

**MS:** Arthralgia, back pain, extremity pain including calcineurin-inhibitor induced pain syndrome

**RESP:** **Acute respiratory distress syndrome**, **atelectasis**, bronchitis, cough increase, dyspnea, **interstitial lung disease**, **lung infiltration**, pleural effusion, **pulmonary embolism or hypertension**, **respiratory distress or failure**

**SKIN:** Flushing, hyperpigmentation, **malignancy**, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** **Anaphylaxis**, cytomegalovirus infection, **hyperkalemia**, **hypokalemia**, **hypomagnesemia**, **hypophosphatemia**, impaired wound healing, **lymphoproliferative or malignant disorders**, **multiorgan failure**, opportunistic infections (including activation of latent viral infections), primary graft dysfunction, weight loss

## Nursing Considerations

- Know that tacrolimus should not be given to patients with congenital long QT syndrome because of increased risk of life-threatening ventricular arrhythmias.
- Know that tacrolimus therapy should not be started within 24 hours of cyclosporine, and vice versa. If tacrolimus or cyclosporine blood levels are elevated beyond 24 hours of either drug being discontinued, know that the other drug should not be started until elevation is resolved.
- Be aware that I.V. tacrolimus therapy should only be given if patient can't tolerate oral tacrolimus. Patient should be switched to oral therapy as soon as possible.
- Do not interchange oral immediate-release capsules with oral extended-release capsules or tablets. Also, do not interchange oral extended-release capsules with oral extended-release tablets, nor interchange capsules with granules.

- Know that drug should not be used simultaneously with cyclosporine, but when used to prevent kidney transplant rejection, it is recommended to be used concomitantly with mycophenolate mofetil. When Hecoria or Prograf formula is used to prevent either kidney or heart transplant rejection, azathioprine may be substituted for mycophenolate mofetil.
- Expect to give drug with adrenal corticosteroid therapy.
- Know that sirolimus should not be administered with tacrolimus because of the potential for severe adverse reactions.
- Be aware that tacrolimus can cause fetal harm. Take special precautions when handling drug.
- To prepare oral suspension, empty the entire contents of each Prograf granules packet into a glass cup. Add 15 to 30 milliliters of room-temperature drinking water to the cup. Mix and administer entire contents of the cup. Know that the granules will not completely dissolve. The suspension should be given immediately after preparation. For younger patients, the suspension can be drawn up via a non-PVC oral syringe that is dispensed with drug. Rinse the cup or syringe with 15 to 30 ml of water and give to patient to ensure that all of the medication is taken. Do not sprinkle Prograf granules on food.
- Dilute intravenous drug with normal saline solution or 5% dextrose to 0.004 to 0.02 mg/ml following manufacturer guidelines. Once diluted, drug should be stored in glass or polyethylene containers (not PVC, because of decreased stability and possible extraction of phthalates). Discard after 24 hours if not used.
- Keep in mind when converting patient from parenteral to oral therapy after heart transplantation, expect to give oral form 8 to 12 hours after infusion is discontinued.
- Be aware that children usually need higher doses of tacrolimus than adults.

**WARNING** Closely monitor patient for anaphylaxis at least during first 30 minutes of I.V. administration. Make sure emergency equipment and drugs, such as aqueous solution of epinephrine and oxygen, are immediately available.

- Monitor patient's blood tacrolimus trough levels regularly, as ordered. Higher trough levels increase risk of toxicity, especially nephrotoxicity and neurotoxicity.

- Monitor blood pressure, especially in patients with history of hypertension, because drug can worsen this condition.
- Monitor results of liver and renal function tests, as ordered, to detect signs of decreased function.
- Know that tacrolimus may increase serum cholesterol, lipid, and triglyceride levels.
- Monitor patient's blood glucose level closely because tacrolimus may cause post-transplant diabetes mellitus with the need for insulin therapy, especially in black and Hispanic patients.
- Monitor patient's serum potassium level, as ordered, because drug can alter it.
- Watch for evidence of neurotoxicity, especially in patients receiving high doses of drug. Evidence of encephalopathy includes headache, impaired consciousness, loss of motor function, psychiatric disturbance, seizures, and tremors.

**WARNING** Monitor patient's ECG and electrolytes, as ordered, periodically throughout tacrolimus therapy because drug may prolong the QT interval, especially in patients with bradyarrhythmias congestive heart failure, electrolyte disturbances, and concomitant use of certain antiarrhythmic drugs.

- Be aware that tacrolimus therapy increases the risk of patient developing serious infections and malignancies. Monitor patient closely, as patient may need to be hospitalized because of life-threatening severity.

## **PATIENT TEACHING**

- Tell patient to inspect her tacrolimus medication when she receives a new prescription and before taking it. If it looks different or dosage instructions have changed, tell patient to alert prescriber, because tacrolimus products are not interchangeable.
- Advise patient to take oral doses of Prograf, 12 hours apart, at same time each day on an empty stomach. Advise patient to take oral doses of extended release form once daily in the morning either 1 hour before a meal or 2 hours after a meal on an empty stomach. Tell patient to swallow capsule or tablet whole and not to chew, divide, or crush capsule or tablet.

Instruct patient or caregiver how to mix and administer Prograf oral granules used to make an oral suspension. Warn not to sprinkle granules on food and to take or administer the suspension immediately after preparation.

- Tell patient to avoid consuming alcohol or grapefruit juice or eating grapefruit while taking tacrolimus.
- Advise patient not to stop taking drug without consulting prescriber.
- Instruct patient not to receive virus vaccines during therapy. Urge him to avoid people who have received such vaccines or to wear a protective mask when he's around them.
- Caution patient to avoid having contact with people who have infections during therapy because tacrolimus causes immunosuppression. Stress importance of notifying prescriber if an infection occurs, as it can become severe. Tell patient to report chills; cough; fever; flu-like symptoms; muscle aches; or painful, red, or warm areas on the skin.
- Warn patient that tacrolimus may cause cancer because of its immunosuppressant action. Tell patient to report any unexplained or unusual signs and symptoms to prescriber.
- Emphasize the importance of having repeated laboratory tests while taking tacrolimus, and urge compliance.
- Inform patient that tacrolimus therapy may result in insulin-dependent diabetes. Tell him to report frequent urination or an increase in fatigue, hunger, or thirst.
- Tell patient to report shortness of breath, swelling anywhere on the body, or tiredness to prescriber.
- Instruct patient to alert all prescribers to tacrolimus therapy and not to take any over-the-counter drugs, including herbal products, without consulting prescriber first.
- Teach patient how to take his blood pressure and provide guidelines for when blood pressure readings should be reported to prescriber.
- Instruct patient to limit exposure to direct sunlight and to wear protective clothing and use sunscreen when exposure can't be avoided.
- Warn women of childbearing age and men who can father a child that tacrolimus can cause fetal harm and to use effective contraceptive measures before starting drug and continuing throughout therapy. If pregnancy occurs, tell both male and female patients to alert prescriber immediately and encourage pregnant women to enroll in the pregnancy exposure registry by calling 1-877-955-6877.

- Tell mothers who wish to breastfeed that tacrolimus has been reported in breast milk and to discuss breastfeeding with prescriber before doing so.

## tadalafil

**Adcirca, Cialis**

### Class and Category

*Pharmacologic class:* Phosphodiesterase-5 (PDE5) inhibitor

*Therapeutic class:* Erectile dysfunction agent

*Pregnancy category:* B

### Indications and Dosages

➤ *To treat erectile dysfunction*

#### **TABLETS (CIALIS)**

**Men.** *Initial:* 10 mg taken 1 hr before sexual activity; dosage decreased to 5 mg or increased to 20 mg, based on clinical response. Alternatively, 2.5 mg once daily, increased to 5 mg once daily, as needed. *Maximum:* 20 mg daily.

***DOSAGE ADJUSTMENT*** For patients who take drug on an as-needed basis and are taking potent CYP3A4 inhibitors such as itraconazole, ketoconazole, or ritonavir, dosage shouldn't exceed 10 mg every 72 hr. For patients taking potent CYP3A4 inhibitors and drug once daily, the maximum recommended dose is 2.5 mg daily. For patients with a creatinine clearance of 30 to 50 ml/min, who take drug on an as-needed basis, initial dosage decreased to 5

mg daily and maximum dosage not to exceed 10 mg every 48 hr. For patients with a creatinine clearance of less than 30 ml/min or who are on hemodialysis, who take drug on an as-needed basis, maximum dose should not exceed 5 mg every 72 hr. Once daily dosing is not recommended for patients with a creatinine clearance less than 30 ml/min. For patients with mild to moderate hepatic dysfunction who take drug on an as-needed basis, dosage should not exceed 10 mg once every day.

➤ *To treat benign prostatic hyperplasia*

## **TABLETS (CIALIS)**

**Men.** 5 mg once daily at approximately the same time every day.

**DOSAGE ADJUSTMENT** For patients taking potent CYP3A4 inhibitors such as itraconazole, ketoconazole, or ritonavir, dosage reduced to 2.5 mg daily. For patients with a creatinine clearance of 30 to 50 mg/ml, initial dosage reduced to 2.5 mg once daily with possible increase to 5 mg, based upon individual response. Drug is not recommended for patients with a creatinine clearance less than 30 ml/min for this indication.

➤ *To treat benign prostatic hyperplasia and erectile dysfunction*

## **TABLETS (CIALIS)**

**Men.** 5 mg once daily, at approximately the same time every day without regard to timing of sexual activity.

**DOSAGE ADJUSTMENT** For patients taking potent CYP3A4 inhibitors such as itraconazole, ketoconazole, or ritonavir, dosage reduced to 2.5 mg daily. For patients with a creatinine clearance of 30 to 50 mg/ml, initial dosage reduced to 2.5 mg once daily with possible increase to 5 mg, based upon individual response. Drug is not

recommended for patients with a creatinine clearance less than 30 ml/min for this indication.

- *To treat pulmonary arterial hypertension in order to improve exercise ability in patients classified as group 1 by the World Health Organization*

## **TABLETS (ADCIRCA)**

**Adults.** 40 mg once daily.

***DOSAGE ADJUSTMENT*** For patients with mild to moderate hepatic or renal impairment or who have already taken ritonavir for at least 1 wk, initial dosage of 20 mg once daily and then increased as tolerated. For patient already taking tadalafil and being prescribed ritonavir, tadalafil temporarily discontinued for at least 24 hours before ritonavir starts. Then, after at least 1 week of ritonavir, tadalafil restarted at 20 mg once daily and then increased to 40 mg once daily, as tolerated.

Route	Onset	Peak	Duration
P.O.	Unknown	30 min–6 hr	Unknown

## **Mechanism of Action**

Enhances the effect of nitric oxide released in the penis during sexual stimulation. Nitric oxide activates the enzyme guanylate cyclase, which causes increased levels of cGMP in the corpus cavernosum. This leads to increased blood flow to the penis, thus producing an erection.

By preventing breakdown of cyclic guanosine monophosphate by phosphodiesterase, levels increase leading to smooth muscle relaxation of the pulmonary vasculature and subsequently, vasodilation. Vasodilation causes the pressure within the pulmonary vasculature to

decrease, which improves tolerance to exercise and delays worsening of pulmonary arterial hypertension.

## **Contraindications**

Concomitant guanylate cyclase stimulator therapy, continuous or intermittent nitrate therapy, hypersensitivity to tadalafil or its components, retinitis pigmentosa

## **Interactions**

### **DRUGS**

*carbamazepine, phenytoin, phenobarbital*: Possibly decreased tadalafil effects

*doxazosin, guanylate cyclase stimulators such as riociguat, tamsulosin and other alpha blockers*: Increased risk of symptomatic hypotension

*erythromycin, itraconazole, ketoconazole, ritonavir*: Prolonged tadalafil effects

*nitrates*: Profound hypotension

*protease inhibitors (other than ritonavir)*: Possibly prolonged tadalafil effects

*rifampin*: Decreased tadalafil effects

### **FOODS**

*grapefruit juice*: Possibly prolonged tadalafil effects

### **ACTIVITIES**

*alcohol use*: Potentiated blood pressure-lowering effects

## **Adverse Reactions**

**CNS:** Asthenia, **CVA**, dizziness, fatigue, headache, hypesthesia, insomnia, migraine, paresthesia, **seizures**, somnolence, syncope, transient global amnesia, vertigo  
**CV:** Angina pectoris, chest pain, hypertension, **hypotension**, **MI**, postural hypotension, palpitations, peripheral edema, **sudden cardiac death**, tachycardia  
**EENT:** Blurred vision, changes in color vision, conjunctivitis, dry mouth, epistaxis, eyelid swelling, eye pain, hearing or visual loss, increased lacrimation, nasal congestion, nasopharyngitis, nonarteritic anterior ischemic optic neuropathy (NAION), pharyngitis, retinal artery or vein occlusion, tinnitus, visual field defects  
**GI:** Diarrhea, dysphagia, dyspepsia, elevated liver enzymes, esophagitis, gastroesophageal reflux, gastritis, increased gamma-glutamyl transpeptidase levels, nausea, upper abdominal pain, vomiting  
**GU:** Priapism, spontaneous penile erection, UTI  
**MS:** Arthralgia, back or neck pain, extremity pain, myalgia  
**RESP:** Bronchitis, cough, dyspnea, upper respiratory tract infection  
**SKIN:** Diaphoresis, **exfoliative dermatitis**, flushing, pruritus, rash, **Stevens-Johnson syndrome**, urticaria  
**Other:** **Angioedema**, flu-like symptoms, **hypersensitivity reactions**

## Nursing Considerations

- Know that patients with hereditary degenerative retinal disorders, including retinitis pigmentosa, should not receive tadalafil because of the risk of serious ophthalmic adverse reactions.
- Be aware that patients with severe hepatic or renal impairment should not receive tadalafil because its effects in these patients are unknown.
- Use tadalafil cautiously in patients with left ventricular outflow obstruction, such as aortic stenosis and idiopathic hypertrophic subaortic stenosis, and those with severely impaired autonomic control of blood

pressure because these conditions increase sensitivity to vasodilators, such as tadalafil.

- Use tadalafil cautiously in patients with conditions that may predispose them to priapism, such as leukemia, multiple myeloma, penile deformities (such as angulation, cavernosal fibrosis, or Peyronie's disease), or sickle cell anemia.
- Monitor blood pressure and heart rate and rhythm before and during therapy.

## PATIENT TEACHING

- Explain that, when used as needed to treat erectile dysfunction, tadalafil should be taken 1 hour before sexual activity to provide the most effective results. Alternatively, if the patient chooses to take a smaller dose of tadalafil daily, encourage him to take it at about the same time every day, regardless of the timing of sexual activity.

**WARNING** Tell patient not to take tadalafil if he takes any form of organic nitrate, either continuously or intermittently, because profound hypotension and death could result.

- Advise patient taking tadalafil to treat erectile dysfunction to obtain sexual counseling to help enhance the drug's effects.
- Urge patient to notify prescriber immediately if erection is painful or lasts longer than 4 hours to avoid possible penile damage and permanent loss of erectile function.
- Advise patient to avoid alcohol or grapefruit juice consumption while taking tadalafil.
- Tell male patients taking tadalafil for pulmonary arterial hypertension not to take another form of tadalafil under the brand name of Cialis or any other PDE5 inhibitors to treat erectile dysfunction.

**WARNING** Tell patient to seek immediate medical attention if he experiences hearing loss that may be accompanied by dizziness or tinnitus or a sudden loss of vision in one or both eyes.

# tamoxifen citrate

**Apo-Tamox (CAN), Nolvadex,  
Soltamox**

## Class and Category

*Pharmacologic class:* Selective estrogen receptor modulator (SERM)

*Therapeutic class:* Anti-estrogen agent

*Pregnancy category:* D

## Indications and Dosages

- *To treat estrogen receptor-positive metastatic breast cancer in men and women*

### ORAL SOLUTION, TABLETS

**Adults.** 20 to 40 mg daily. Dosages greater than 20 mg administered twice daily.

- *As adjuvant treatment for early-stage estrogen receptor-positive breast cancer; to reduce occurrence of contralateral breast cancer when used as adjuvant therapy for the treatment of breast cancer*

### ORAL SOLUTION, TABLETS

**Adults.** 20 mg daily for 5 to 10 years.

- *To reduce the risk of invasive breast cancer in women with ductal carcinoma in situ (DCIS) after radiation*

*and surgery; to reduce the risk of breast cancer in women at high risk*

## **ORAL SOLUTION, TABLETS**

**Adults.** 20 mg daily for 5 yr.

## **Mechanism of Action**

May block the effects of estrogen on breast tissue by competing with estrogen for estrogen-receptor binding sites. Estrogen may stimulate the growth of cancer cells.

## **Contraindications**

Hypersensitivity to tamoxifen or its components; women at high risk for breast cancer and women with DCIS and a history of deep vein thrombosis or pulmonary embolus or who need coumarin-type anticoagulant therapy

## **Interactions**

### **DRUGS**

*bromocriptine:* Possibly increased blood tamoxifen level

*estrogens:* Possibly altered therapeutic effect of tamoxifen

*warfarin and other coumarin-type anticoagulants:*

Increased anticoagulant effect of these drugs

## **Adverse Reactions**

**CNS:** Confusion, **CVA**, depression, dizziness, fatigue, headache, light-headedness, somnolence, weakness

**CV:** Edema, hyperlipidemia, **thrombosis**

**EENT:** Keratopathy, ocular toxicity (including cataracts), optic neuritis, retinopathy

**GI:** Elevated liver enzymes, **hepatotoxicity**, nausea, vomiting

**GU:** **Endometrial cancer**, endometrial hyperplasia, endometrial polyps, genital itching, menstrual irregularities, ovarian cysts, vaginal discharge (females); impotence, decreased libido (males)

**HEME:** Anemia, **leukopenia**, **thrombocytopenia**

**MS:** Transient bone or tumor pain

**RESP:** **Pulmonary embolism**

**SKIN:** Bullous pemphigoid, dry skin, **erythema multiforme**, rash, **Stevens-Johnson syndrome**, thinning hair

**Other:** **Angioedema**, hot flashes, **hypercalcemia**, weight gain

## Nursing Considerations

**WARNING** Make sure that patient has been informed about serious or potentially life-threatening adverse effects associated with tamoxifen before therapy begins. Be aware that women with ductal carcinoma in situ and those at high risk for breast cancer are more likely to develop pulmonary emboli, stroke, or uterine cancer than others receiving tamoxifen.

- Know that if patient is premenopausal, drug therapy should begin in the middle of menstruation; if patient's menstrual cycles are irregular, verify that she has had a negative pregnancy test before therapy starts.
- Expect patient to undergo an ophthalmic examination before and periodically during tamoxifen therapy. Also expect to monitor patient for adverse ocular reactions, such as cataracts.
- Assess patient for signs and symptoms of thromboembolic events, such as change in mental status, leg pain, or shortness of breath.

- Periodically monitor patient's cholesterol and triglyceride levels, liver enzymes, and platelet and WBC counts, as ordered.
- Monitor blood calcium level and assess patient for signs and symptoms of hypercalcemia, such as nausea, thirst, and vomiting; tamoxifen may cause hypercalcemia in breast cancer patients with bone metastasis within a few weeks of starting treatment.
- Store tamoxifen in a closed, light-resistant container at room temperature.

## **PATIENT TEACHING**

- Advise patient to swallow tamoxifen tablet whole with water.
- Instruct premenopausal patient to use a nonhormonal form of contraception, such as a condom or diaphragm, during tamoxifen therapy. Emphasize that she shouldn't become pregnant while taking drug and for 2 months afterward. Advise her to notify prescriber at once if she becomes pregnant during therapy.
- Inform patient of the most common side effects—hot flashes, irregular menses, and vaginal discharge.
- Urge patient to immediately notify prescriber if she notices difficulty breathing, facial swelling, itching, or a rash, because they may signify a hypersensitivity reaction.
- Advise patient to notify prescriber if she experiences calf swelling or leg pain during tamoxifen therapy, because they may indicate a blood clot.
- Instruct patient to report signs of hepatotoxicity, such as flu-like symptoms, nausea, tiredness, or yellow skin.
- Advise patient to have regular gynecologic examinations and to notify prescriber about abnormal symptoms, including abdominal or pelvic pain, new breast lumps, and unusual vaginal bleeding or discharge.
- Urge patients who take tamoxifen for prophylaxis to have regular mammograms, because tamoxifen doesn't prevent all breast cancers.
- Emphasize the importance of taking tamoxifen regularly. Urge patient to consult prescriber if adverse reactions, such as nausea and vomiting, are interfering with dosage schedule. These symptoms may be a sign of hypercalcemia.
- Inform women who wish to breastfeed that tamoxifen may appear in breast milk and cause serious adverse effects in the infant.

# tamsulosin hydrochloride

**Flomax**

## Class and Category

*Pharmacologic class:* Alpha adrenergic antagonist

*Therapeutic class:* Benign prostatic hyperplasia (BPH) agent

*Pregnancy category:* B

## Indications and Dosages

➤ *To treat BPH*

### CAPSULES

**Adults.** *Initial:* 0.4 mg daily 30 min after same daily meal for 2 to 4 wk, increased to 0.8 mg daily if no response to initial dosage. *Maximum:* 0.8 mg daily.

## Mechanism of Action

Blocks  $\alpha_1$ -adrenergic receptors in the prostate. This action inhibits smooth-muscle contraction in the bladder neck and prostate, prostatic capsule, and prostatic urethra, which improves the rate of urine flow and reduces symptoms of BPH.

## Contraindications

Hypersensitivity to tamsulosin, quinazolines, or their components

## Interactions

### DRUGS

*alpha blockers*: Additive effects of both drugs

*cimetidine*: Risk of decreased tamsulosin clearance

*CYP2D6 inhibitors (such as fluoxetine, paroxetine, terbinafine), CYP3A4 inhibitors (such as erythromycin, ketoconazole)*: Possibly increased plasma tamsulosin level

*phosphodiesterase-5 inhibitors*: Increased risk of hypotension

## Adverse Reactions

**CNS**: Asthenia, dizziness, drowsiness, headache, insomnia, syncope, vertigo

**CV**: **Arrhythmia**, **atrial fibrillation**, chest pain, orthostatic hypotension, palpitations, tachycardia

**EENT**: Amblyopia, diplopia, dry mouth, epistaxis, intraoperative floppy iris syndrome (during cataract and glaucoma surgery), pharyngitis, rhinitis, visual impairment

**GI**: Constipation, diarrhea, nausea, vomiting

**GU**: Decreased libido, ejaculation disorders, priapism

**MS**: Back pain

**RESP**: Dyspnea, **respiratory impairment**

**SKIN**: Desquamation, **erythema multiforme**, **exfoliative dermatitis**, pruritus, rash, **Stevens-Johnson syndrome**, urticaria

**Other**: **Angioedema**

## Nursing Considerations

- Be aware that prostate cancer should be ruled out before tamsulosin therapy begins.
- Give drug about 30 minutes after the same meal each day.
- Know that if patient takes drug on an empty stomach, his blood pressure should be monitored because of the increased risk of orthostatic hypotension.
- Be aware that if patient doesn't take drug for several days, therapy should be resumed at 0.4 mg/dose, as prescribed.

## PATIENT TEACHING

- Instruct patient not to chew, crush, or open tamsulosin capsules and to take drug about 30 minutes after the same meal each day.
- Instruct patient to notify prescriber if he misses several days of therapy, and caution him against restarting drug at previous dosage.
- Advise patient to avoid potentially hazardous activities until drug's CNS effects are known. Mention the need for caution if dosage is increased.
- Advise patient to change position slowly, especially after initial dose and each dosage increase, to minimize effects of orthostatic hypotension.
- Tell patient to inform ophthalmologist of tamsulosin therapy because drug may increase risk for complications with cataract surgery.

# telavancin

## Vibativ

## Class and Category

*Pharmacologic class:* Lipoglycopeptide

*Therapeutic class:* Antibiotic

*Pregnancy category:* C

## Indications and Dosages

- *To treat complicated skin and skin structure infections caused by gram-positive organisms: Enterococcus faecalis (vancomycin-susceptible isolates only), Staphylococcus aureus, Streptococcus agalactiae, S. anginosus group (includes S. anginosus, S. constellatus, and S. intermedius), and S. pyogenes (S. aureus, S. pyogenes, S. agalactiae, S. anginosus group [includes S. anginosus, S. intermedius, and S. constellatus]), or E. faecalis (vancomycin-susceptible isolates only)*

### I.V. INFUSION

**Adults.** 10 mg/kg administered over 60 min every 24 hr for 7 to 14 days

- *To treat hospital-acquired and ventilator-associated bacterial pneumonia caused by S. aureus when alternative treatments are not suitable*

### I.V. INFUSION

**Adults.** 10 mg/kg administered over 60 min every 24 hr for 7 to 21 days.

***DOSAGE ADJUSTMENT*** For patients with creatinine clearance of 30 to 50 ml/min/1.73m, dosage reduced to 7.5 mg/kg every 24 hours. For patient with creatinine clearance of at least 10 but less than 30 ml/min, 10 mg/kg every 48 hours.

Route	Onset	Peak	Duration
I.V.	Unknown	1-2 hr	24 hr

## Mechanism of Action

Inhibits cell wall synthesis and alters the permeability of bacterial membranes, causing cell wall lysis and cell death.

## Incompatibilities

Don't mix telavancin with other drugs or I.V. solutions containing additives. If administration must be through the same I.V. line, flush the line with 5% dextrose injection, 0.9% sodium chloride injection, or lactated Ringer's injection before and after infusing telavancin.

## Contraindications

Hypersensitivity to telavancin or its components, intravenous unfractionated heparin sodium

## Interactions

### DRUGS

*ACE inhibitors, loop diuretics, NSAIDs:* Increased risk of nephrotoxicity

*drugs known to prolong the QT interval, such as clarithromycin, disopyramide, erythromycin, quinidine:* Increased risk of prolonged QT interval

## Adverse Reactions

**CNS:** Dizziness, rigors

**CV:** **Prolonged QT interval**

**EENT:** Taste disturbance

**GI:** Abdominal pain, anorexia, diarrhea, ***Clostridium difficile-associated diarrhea***, nausea, vomiting

**GU:** Elevated creatinine level, foamy urine, **nephrotoxicity**

**HEME:** **Abnormal coagulation**

**SKIN:** Pruritus, rash

**Other:** **Anaphylaxis**, infusion-related reactions such as erythema or pain

## Nursing Considerations

- Know that telavancin isn't recommended for patients with congenital long-QT syndrome, severe left ventricular hypertrophy, uncompensated heart failure or who currently have a prolonged QT interval because it may prolong the QT interval, causing life-threatening complications.
- Know that use of intravenous unfractionated heparin sodium is contraindicated with telavancin because the activated partial thromboplastin time (aPTT) test results may be falsely prolonged for up to 18 hours after telavancin administration.
- Use cautiously in patients taking drugs known to prolong the QT interval because of increased risk of a prolonged QT interval.
- Make sure woman of childbearing age has a negative pregnancy test result before starting telavancin because of risk of fetal harm.
- Obtain baseline serum creatinine level before telavancin therapy starts because preexisting moderate to severe renal impairment may increase mortality in the presence of telavancin therapy and is not recommended in such patients unless the benefit outweighs the potential risk. Expect to, monitor patient's serum creatinine level throughout therapy, as ordered, because drug may cause nephrotoxicity, especially in patients with congestive heart failure, diabetes mellitus, hypertension, or preexisting renal disease and in patients taking such nephrotoxic drugs as ACE inhibitors, loop diuretics, and NSAIDs. If renal function declines, notify prescriber and expect to discontinue telavancin.
- Dilute a 250-mg vial with 15 ml or a 750-mg vial with 45 ml of a diluent such as 5% dextrose injection, sterile water for injection, or 0.9% sodium chloride injection to obtain a solution of 15 mg/ml. When ready to administer drug, further dilute doses of 150 to 800 mg in 100 to 250 ml of 5% dextrose injection, 0.9% sodium chloride injection, or lactated Ringer's injection before infusion. Doses less than 150 mg or greater than 800 mg should be further diluted in a volume that yields a final concentration of 0.6 to 0.8 mg/ml.
- Use telavancin within 4 hours of the time it is reconstituted in the vial (including its transfer to an infusion bag for further dilution) if kept at room temperature and 72 hours if refrigerated. Discard if time limit exceeds these parameters.

- Infuse telavancin over 60 minutes because more rapid infusion may cause a reaction like red-man syndrome, which causes flushing of upper body, pruritus, rash or urticaria. If present, stop or slow infusion to resolve.
- Monitor patient for hypersensitivity reactions during and after infusion of drug. Stop infusion at first sign of skin rash or any other hypersensitivity sign and notify prescriber.
- Monitor patient for diarrhea, which may range from mild to severe and may occur more than 2 months after antibiotic is discontinued. Report diarrhea and, if *C. difficile* is suspected, expect telavancin to be discontinued. Provide supportive care, such as antibiotic therapy to treat *C. difficile*, electrolyte and fluid replacement, protein supplementation, and possibly surgical intervention, as needed.
- Be aware that while telavancin doesn't interfere with coagulation, it does interfere with certain tests used to monitor coagulation, such as activated clotting time, APTT, coagulation-based factor Xa tests, INR, and PT. Collect blood samples for coagulation tests as close as possible to administration of next dose of telavancin to minimize interference.

## PATIENT TEACHING

- Instruct women of childbearing age to use effective contraception during telavancin therapy.
- Caution patient that diarrhea may occur more than 2 months after antibiotic has been discontinued and to report any persistent or severe episodes to prescriber.
- Warn patient that drug may cause urine to be foamy and taste to be altered.
- Advise patient to alert all prescribers that he takes telavancin because some drugs may interact with it, causing serious adverse effects.

**telbivudine**

**Tyzeka**

## Class and Category

*Pharmacologic class:* Nucleoside analogue

*Therapeutic class:* Antiviral

*Pregnancy category:* B

## Indications and Dosages

- *To treat chronic hepatitis B in patients with evidence of viral replication and either evidence of persistent elevations in serum aminotransferases (ALT or AST) or histologically active disease*

### ORAL SOLUTION, TABLETS

**Adults and adolescents age 16 and over.** 600 mg tablet or 30 ml of oral solution once daily.

***DOSAGE ADJUSTMENT*** For patient with renal impairment and a creatinine clearance between 30 and 40 ml/min, oral solution dosage decreased to 20 ml once daily or 600-mg tablet taken every 48 hours. For patient with renal impairment and a creatinine clearance less than 30 ml/min but not requiring dialysis, oral solution dosage decreased to 10 ml once daily or 600-mg tablet taken every 72 hours. For patient with end-stage renal disease, oral solution decreased to 6 ml once daily or 600-mg tablet taken every 96 hours.

## Mechanism of Action

After being phosphorylated by cellular kinases to the active triphosphate form, telbivudine is incorporated into hepatitis B viral DNA, causing DNA chain termination.

## Contraindications

Coadministration with pegylated interferon alfa-2a, hypersensitivity to telbivudine or its components

## Interactions

### DRUGS

*drugs that alter renal function, such as aminoglycosides and NSAIDs:* Possibly increased risk of nephrotoxicity

*pegylated interferon alfa-2a:* Increased risk of peripheral neuropathy occurrence and severity

## Adverse Reactions

**CNS:** Dizziness, fatigue, fever, headache, hypoesthesia, insomnia, paresthesia, peripheral neuropathy

**EENT:** Pharyngolaryngeal pain

**GI:** Abdominal distention or pain, diarrhea, dyspepsia, elevated liver and pancreatic enzymes, **hepatitis B exacerbation**, hyperbilirubinemia, nausea, **severe hepatomegaly with steatosis**

**HEME:** **Neutropenia, thrombocytopenia**

**MS:** Arthralgia, back pain, elevated creatine kinase (CK) level, myalgia, myopathy, myositis, muscle weakness, **rhabdomyolysis**

**RESP:** Cough

**SKIN:** Pruritus, rash

**Other:** **Lactic acidosis**

## Nursing Considerations

- Expect to monitor HBV DNA every 6 months to check effectiveness of telbivudine. If patient tests positive for HBV DNA at any time during treatment, expect telbivudine to be discontinued and alternative therapy prescribed. In addition, if patient demonstrates incomplete viral

suppression (HBV DNA greater than or equal to 300 copies per ml) after 24 weeks of treatment, expect drug to be discontinued and an alternate therapy prescribed.

**WARNING** Know that lactic acidosis and severe hepatomegaly with steatosis have occurred with telbivudine therapy and that death has occurred in some patients. Risk factors include presence of obesity, prolonged nucleoside exposure, and being a woman. However, know that lactic acidosis and severe hepatomegaly with steatosis have also occurred in patients with no known risk factors. Expect drug to be discontinued in any patient who develops clinical or laboratory findings suggestive of lactic acidosis or pronounced hepatotoxicity, even in the absence of marked transaminase elevations.

- Expect to monitor patient's liver enzymes, as ordered, throughout therapy and for several months after telbivudine has been discontinued, because severe acute exacerbations of hepatitis B have occurred in patients who have discontinued anti-hepatitis B therapy, including telbivudine.
- Monitor patient for unexplained persistent muscle aches and/or muscle weakness in conjunction with increases in CK values, because telbivudine therapy has been associated with myopathy and rhabdomyolysis. If present, notify prescriber and expect drug to be withheld during testing and discontinued if myopathy is confirmed.
- Be aware that if patient develops signs and symptoms of peripheral neuropathy (burning, numbness, or tingling sensations in the arms and/or legs with or without gait disturbance), telbivudine can be expected to be withheld during testing and discontinued if peripheral neuropathy is confirmed.

## **PATIENT TEACHING**

- Stress importance of not missing a dose, as resistance to drug can develop. Also tell patient to take drug exactly as prescribed.
- Tell patient to keep tablets and oral solution in their original container and store at room temperature. Remind patients taking oral solution to use the oral solution within 2 months after opening the bottle.

- Advise patient to dispose of drug when it is outdated or no longer needed by taking it to a community take-back disposal program, if available, or by placing it in a closed container such as a sealed bag in the household trash after removing all identifying information from the original container before throwing it out.
- Instruct patient not to discontinue telbivudine therapy without consulting prescriber, because deterioration of liver disease may occur.
- Remind patient that telbivudine therapy is not a cure for hepatitis B.
- Stress importance of promptly reporting unexplained muscle aches, pain, tenderness, or weakness, as well as any persistent, severe, or unusual signs and symptoms.
- Tell patient to report any burning sensations, numbness, or tingling in his arms and/or legs with or without gait disturbance.
- Emphasize importance of keeping telbivudine out of the reach of children.
- Alert patient on a low-sodium diet that telbivudine oral solution contains about 47 mg of sodium per 30 ml.
- Encourage women who become pregnant while taking telbivudine to enroll in the pregnancy exposure registry by calling 1-800-258-4263.

**telmisartan**

**Micardis**

## **Class and Category**

*Pharmacologic class:* Angiotensin II receptor blocker (ARB)

*Therapeutic class:* Antihypertensive

*Pregnancy category:* D

## **Indications and Dosages**

- *To manage hypertension, alone or with other antihypertensives*

## TABLETS

**Adults.** *Initial:* 40 mg daily. *Maintenance:* 20 to 80 mg daily. *Maximum:* 80 mg daily.

- *To reduce risk of MI, stroke, or death from cardiovascular causes in patients at high risk who are unable to take ACE inhibitors*

## TABLETS

**Adults age 55 and over.** 80 mg once daily.

Route	Onset	Peak	Duration
P.O.	Unknown	In 4 wk	Unknown

## Mechanism of Action

Blocks angiotensin II from binding to receptor sites in many tissues, including adrenal glands and vascular smooth muscle. This action inhibits the aldosterone-secreting and vasoconstrictive effects of angiotensin II, which reduces blood pressure.

## Contraindications

Concurrent aliskiren therapy in patients with diabetes or renal impairment (GFR less than 60 ml/min), hypersensitivity to telmisartan or its components

## Interactions

## DRUGS

*ACE inhibitors, aliskiren, other angiotensin receptor blockers:* Increased risk of hyperkalemia, hypotension, and renal dysfunction  
*digoxin:* Increased peak blood digoxin level and risk of digitalis toxicity  
*diuretics, other antihypertensives:* Enhanced hypotensive effect  
*lithium:* Increased serum lithium levels and toxicity  
*NSAIDs:* Increased risk of renal dysfunction in elderly patients and those with volume depletion and existing renal dysfunction  
*potassium-sparing diuretics, potassium supplements:* Increased risk of hyperkalemia  
*ramipril:* Increased serum ramipril level; decreased telmisartan level

## **FOOD**

*salt substitutes containing potassium:* Increased risk of hyperkalemia

## **Adverse Reactions**

**CNS:** Asthenia, dizziness, fatigue, headache, syncope, weakness

**CV:** **Atrial fibrillation**, **bradycardia**, chest pain, **congestive heart failure**, hypertension, **hypotension**, **MI**, orthostatic hypotension, peripheral edema

**EENT:** Pharyngitis, sinusitis

**ENDO:** **Hypoglycemia** (in diabetics)

**GI:** Abdominal pain, diarrhea, elevated liver enzymes, indigestion, nausea, vomiting

**GU:** **Acute renal failure**, erectile dysfunction, renal dysfunction, UTI

**HEME:** Anemia, eosinophilia, **thrombocytopenia**

**MS:** Back pain, leg or muscle cramps, myalgia, tendinitis, tendon pain, tenosynovitis

**RESP:** ACE cough, upper respiratory tract infection

**SKIN:** Diaphoresis, erythema, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, elevated uric acid level, flu-like symptoms, **hyperkalemia**, hypovolemia

## Nursing Considerations

- Give telmisartan cautiously to patients with dehydration or hyponatremia.
- Expect prescriber to add a diuretic to regimen if patient's blood pressure isn't well controlled by telmisartan.
- Check patient's blood pressure regularly. Be prepared to treat symptomatic hypotension by placing patient in supine position and giving normal saline solution, as ordered.
- Monitor BUN and serum creatinine levels and urine output in patients with impaired renal function because they're at increased risk for oliguria, progressive azotemia, and possibly acute renal failure.
- Monitor liver enzymes, as appropriate, and assess for evidence of drug toxicity in patients with severe hepatic disease because they're at increased risk for toxicity from increased drug accumulation.
- Avoid using telmisartan in pregnant women during second and third trimesters because drug can increase the risk of fetal harm.

## PATIENT TEACHING

- Advise patient to avoid hazardous activities until telmisartan's CNS effects are known.
- Instruct patient to change position slowly to minimize effects of orthostatic hypotension.
- Urge patient to immediately notify prescriber about diarrhea, dizziness, severe nausea, or vomiting.
- Instruct patient to consult prescriber before taking any new drug.
- Advise patient not to use potassium supplements or salt substitutes that contain potassium without checking with prescriber first.

- Advise patient to drink adequate amounts of fluid during hot weather and when exercising.
- Advise female patients of childbearing age to notify prescriber immediately about known or suspected pregnancy.
- Inform mothers not to breastfeed their infant because serious adverse reactions may occur in the breastfed infant.

# temazepam

## Restoril

### Class, Category, and Schedule

*Pharmacologic class:* Benzodiazepine

*Therapeutic class:* Sedative-hypnotic

*Pregnancy category:* X *Controlled substance schedule:* IV

### Indications and Dosages

➤ *To provide short-term management of insomnia*

#### CAPSULES

**Adults.** 7.5 to 30 mg 30 min before bedtime. *Maximum:* 30 mg daily.

***DOSAGE ADJUSTMENT*** For elderly or debilitated patients, 7.5 mg 30 min before bedtime. *Maximum:* 15 mg daily.

### Mechanism of Action

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding

to specific benzodiazepine receptor sites in cortical and limbic areas of the CNS. By binding to these receptor sites, temazepam increases GABA's inhibitory effects and blocks cortical and limbic arousal.

## **Contraindications**

Hypersensitivity to temazepam, other benzodiazepines, or their components; pregnancy

## **Interactions**

### **DRUGS**

*antihistamines (such as brompheniramine, carbinoxamine, chlorpheniramine, clemastine, cyproheptadine, diphenhydramine, trimeprazine), anxiolytics, barbiturates, general anesthetics, opioid analgesics, other*

*benzodiazepines, phenothiazines, promethazine, sedating antihistamines, sedative-hypnotics, tramadol, tricyclic*

*antidepressants*: Increased respiratory depression or sedation, which could become severe

*clozapine*: Risk of respiratory depression or arrest

*digoxin*: Increased risk of elevated blood digoxin level and digitalis toxicity

*flumazenil*: Increased risk of withdrawal symptoms

*levodopa*: Possibly decreased levodopa effects

*oral contraceptives*: Decreased response to temazepam

*phenytoin*: Possibly phenytoin toxicity

*probenecid*: Increased response to temazepam

*zidovudine*: Possibly zidovudine toxicity

### **ACTIVITIES**

*alcohol use:* Increased CNS and respiratory depression including apnea

*smoking:* Increased temazepam clearance

## Adverse Reactions

**CNS:** Aggressiveness, anxiety (in daytime), ataxia, complex behaviors (such as sleep driving), confusion, decreased concentration, depression, dizziness, drowsiness, euphoria, fatigue, headache, insomnia, nightmares, slurred speech, **suicidal ideation**, syncope, talkativeness, tremor, vertigo, wakefulness during last third of night

**CV:** Palpitations, tachycardia

**EENT:** Abnormal or blurred vision, increased salivation, **throat tightness**

**GI:** Abdominal pain, constipation, diarrhea, hepatic dysfunction, jaundice, nausea, thirst, vomiting

**GU:** Decreased libido

**HEME:** **Agranulocytosis**, anemia, **leukopenia**, **neutropenia**, **thrombocytopenia**

**MS:** Muscle spasm or weakness

**RESP:** Dyspnea, increased bronchial secretions

**SKIN:** Diaphoresis, flushing, pruritus, rash

**Other:** **Anaphylaxis**, **angioedema**, physical and psychological dependence

## Nursing Considerations

- Use temazepam cautiously in patients with a history of depression or suicidal thoughts.

**WARNING** Monitor patient closely for evidence of hypersensitivity reaction, such as dyspnea, nausea, swelling, throat tightness, and vomiting. If present,

discontinue temazepam immediately, notify prescriber, and provide supportive care.

- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times and could lead to suicidal ideation.

**WARNING** Monitor patient for evidence of physical and psychological dependence during therapy.

- Implement safety precautions, according to facility policy, especially in elderly patients, because they're more sensitive to drug's CNS effects.
- Assess patients with respiratory depression, severe COPD, or sleep apnea for signs of ventilatory failure.
- Be aware that temazepam can aggravate acute intermittent porphyria, myasthenia gravis, and severe renal impairment.
- Be aware that temazepam may cause deterioration of cognition or coordination in patients with late-stage Parkinson's disease or worsening psychosis.
- Be aware that drug shouldn't be discontinued abruptly, even after only 1 to 2 weeks of therapy, because doing so may cause seizures or withdrawal symptoms, such as insomnia, irritability, and nervousness.

**WARNING** Know that opioids should only be used concomitantly with benzodiazepine therapy in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of the opioid to be limited. Monitor patient closely for signs and symptoms of a decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

## **PATIENT TEACHING**

- Instruct patient to take temazepam exactly as prescribed and not to stop or change dosage without consulting prescriber.
- Explain the risks associated with abrupt cessation, including abdominal cramps, acute sense of hearing, confusion, depression, nausea, numbness, perceptual disturbances, photophobia, sweating, tachycardia, tingling, trembling, and vomiting.
- Advise patient to avoid consuming alcohol because it increases drug's sedative effects and the risk of such abnormal behaviors as sleep driving. Also, tell patient that combining alcohol or a benzodiazepine such as temazepam with an opioid could result in severe respiratory depression and even death.
- Caution patient about possible drowsiness. Advise her to avoid potentially hazardous activities until drug's CNS effects are known.
- Urge patient to notify prescriber immediately about excessive drowsiness, nausea, and known or suspected pregnancy.
- Instruct patient to stop taking temazepam and seek emergency care if she experiences abnormal swelling, difficulty breathing, nausea, throat tightness, or vomiting.
- Advise patient that drug may cause abnormal behaviors during sleep, such as driving a car, eating, talking on the phone, or having sex without any recall of the event. If family notices any such behavior or patient sees evidence of such behavior upon awakening, the prescriber should be notified.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Instruct patient to inform all prescribers of temazepam use, especially when pain medication may be prescribed.

**tenecteplase**

**TNKase**

## **Class and Category**

*Pharmacologic class:* Tissue plasminogen activator (tPA)

*Therapeutic class:* Thrombolytic

*Pregnancy category:* C

## Indications and Dosages

➤ *To reduce mortality associated with acute MI*

### I.V. INJECTION

**Adults.** Single bolus administered over 5 sec in individualized dosage based on patient's weight, as follows: 50 mg (10 ml) for patients weighing 90 kg (198 lb) or more; 45 mg (9 ml) for patients weighing 80 to 89 kg (176 to 196 lb); 40 mg (8 ml) for patients weighing 70 to 79 kg (154 to 174 lb); 35 mg (7 ml) for patients weighing 60 to 69 kg (132 to 152 lb); 30 mg (6 ml) for patients weighing less than 60 kg (132 lb). *Maximum:* 50 mg total dose.

## Mechanism of Action

Binds to fibrin and converts plasminogen to plasmin. Plasmin breaks down fibrin, fibrinogen, and other clotting factors, resulting in dissolution of a coronary artery thrombus.

## Incompatibilities

Don't administer tenecteplase through an I.V. line containing dextrose because precipitation may occur.

## Contraindications

Active internal bleeding, aneurysm, arteriovenous malformation, bleeding disorders, brain tumor, history of

cerebrovascular accident, hypersensitivity to tenecteplase or its components, intracranial or intraspinal surgery or trauma within past 2 months, severe uncontrolled hypertension

## Interactions

### DRUGS

*abciximab, aspirin, clopidogrel, dipyridamole, heparin, oral anticoagulants, ticlopidine:* Possibly increased risk of bleeding

## Adverse Reactions

**CNS:** Intracranial hemorrhage

**EENT:** Epistaxis, gingival bleeding, laryngeal edema, pharyngeal bleeding

**GI:** GI and retroperitoneal bleeding

**GU:** Genitourinary bleeding, prolonged or heavy menstrual bleeding

**HEME:** Hematoma

**RESP:** Hemoptysis

**SKIN:** Bleeding at puncture sites, surgical incision sites, or venous cutdown sites; rash; urticaria

**OTHER:** Anaphylaxis, angioedema

## Nursing Considerations

**WARNING** Reconstitute tenecteplase for injection immediately before use because drug contains no antibacterial preservatives. If reconstituted drug isn't used immediately, refrigerate vial at 2° to 8° C (36° to 46° F). Discard solution if not used within 8 hours.

- Use the supplied 10-ml syringe with dual cannula device to reconstitute and administer drug. Withdraw 10 ml of supplied (preservative-free) sterile water for injection into syringe, and inject entire contents into vial containing tenecteplase dry powder, directing stream of diluent into powder. Gently swirl—don't shake—vial until contents are completely dissolved. If slight foaming occurs during reconstitution, allow drug to stand undisturbed for a few minutes to allow large bubbles to dissipate. Then withdraw prescribed dose of tenecteplase from reconstituted drug in vial, using supplied syringe. Make sure that reconstituted preparation is a colorless to pale yellow transparent solution. Discard any unused solution.
- Give drug as a single I.V. bolus over 5 seconds. Although supplied syringe is intended for use with needleless I.V. systems, be aware that it is also compatible with a conventional needle. Follow manufacturer's directions for use with each system. Flush any dextrose-containing I.V. lines with saline solution before and after administering tenecteplase.
- Monitor patient during and for several hours after tenecteplase has been administered for hypersensitivity reactions which may include anaphylaxis, angioedema, laryngeal edema, rash, and urticaria. If symptoms occur, notify prescriber, expect drug therapy to be discontinued, and provide supportive care, as prescribed.

**WARNING** Monitor patient for evidence of GI bleeding, including bloody or black, tarry stools; bloody or coffee-ground vomitus; and severe stomach pain. Notify prescriber immediately if any of these signs or symptoms develops.

- Assess tenecteplase injection site for signs and symptoms of hematoma, including dark, deep purple bruises under skin and itching, pain, redness, or swelling. Also monitor patient for delayed bleeding at puncture sites, bleeding from surgical incisions, and superficial bleeding.
- Assess for signs and symptoms of genitourinary bleeding (such as hematuria), intracranial bleeding (such as decreased level of consciousness), respiratory tract bleeding (such as hemoptysis), or retroperitoneal bleeding (such as abdominal pain or swelling or back pain). Notify prescriber immediately if patient develops any of these signs or symptoms.
- If serious bleeding (not controllable by local pressure) occurs, expect to discontinue concomitant heparin or oral antiplatelet therapy immediately.
- Avoid I.M. injections and nonessential handling of patient, if possible, for first few hours after drug administration.

- Know that if arterial puncture becomes necessary during first few hours after tenecteplase administration, you should expect to use an upper extremity that's accessible to manual compression. Apply pressure for at least 30 minutes after procedure, use a pressure dressing, and frequently monitor puncture site for signs of bleeding.
- Monitor patients at higher risk for thromboembolism, such as patients with atrial fibrillation or mitral stenosis, while receiving a thrombolytic such as tenecteplase.

## PATIENT TEACHING

- Advise patient to immediately report any bleeding, including from gums or nose.
- Instruct patient to limit physical activity during tenecteplase administration to reduce the risk of bleeding or injury.

## tenofovir disoproxil fumarate

**Viread**

## Class and Category

*Pharmacologic class:* Nucleoside reverse transcriptase inhibitor (NRTI)

*Therapeutic class:* Antiretroviral

*Pregnancy category:* B

## Indications and Dosages

- *As adjunct to treat human immunodeficiency virus type 1 (HIV-1) infection; to treat chronic hepatitis B*

*virus (HBV)*

## **ORAL POWDER, TABLETS**

**Adults and children weighing at least 35 kg (77 lb).**  
300 mg once daily.

**Adults and children age 2 and over weighing less than 35 kg (77 lb) but at least 10 kg (22 lb).** 8 mg/kg once daily. *Maximum:* 300 mg once daily.

***DOSAGE ADJUSTMENT*** For adult patient with a creatinine clearance between 30 and 49 ml/min, dosage interval increased to every 48 hr. For adult patient with a creatinine clearance between 10 and 29 ml/min, dosage interval increased to every 72 to 96 hr. For hemodialysis patient, dosage interval increased to every 7 days or after a total of approximately 12 hours of dialysis. There are no specific recommendations for children with renal dysfunction.

## **Mechanism of Action**

Inhibits the activity of HIV-1 reverse transcriptase and HBV reverse transcriptase by competing with the natural substrate deoxyadenosine 5' triphosphate and, after incorporation into DNA, by DNA chain termination.

## **Contraindications**

Hypersensitivity to tenofovir disoproxil fumarate or its components

## **Interactions**

### **DRUGS**

*adeфовir dipivoxil:* Increased blood tenofovir level increasing risk of adverse reactions

*atazanavir*: Decreased atazanavir concentration decreasing drug effectiveness

*atazanavir/ritonavir, darunavir/ritonavir,*

*ledipasvir/sofosbuvir, lopinavir/ritonavir,*

*sofosbuvir/velpatasvir, sofosbuvir/velpatasvir/voxilaprevir*:

Increased tenofovir concentration with increased risk of adverse reactions

*didanosine*: Increased concentration of didanosine with increased risk of adverse reactions

*drugs affecting renal function, such as aminoglycosides,*

*acyclovir, cidofovir, ganciclovir, high-dose or multiple*

*NSAIDs use, valacyclovir, valganciclovir*: Possibly increased concentration of tenofovir and/or increased concentration of other renally eliminated drugs

## **Adverse Reactions**

**CNS**: Anxiety, asthenia, depression, dizziness, fatigue, fever, headache, insomnia, peripheral neuropathy

**CV**: Chest pain, elevated cholesterol and triglycerides

**EENT**: Nasopharyngitis, sinusitis

**ENDO**: Hyperglycemia

**GI**: Abdominal pain, **acute hepatitis (severe)**, anorexia, diarrhea, dyspepsia, elevated liver and pancreatic enzymes, flatulence, **hepatomegaly with steatosis (severe)**, nausea, **pancreatitis**, vomiting

**GU**: **Acute renal failure, acute tubular necrosis**, elevated creatinine, **Fanconi syndrome**, hematuria, interstitial nephritis, **renal impairment**

**HEME**: Anemia, **neutropenia**

**MS**: Arthralgia, back pain, decreased bone density, elevated bone specific alkaline phosphatase and creatine kinase, muscular weakness, myalgia, myopathy, osteomalacia, **rhabdomyolysis**

**RESP:** Dyspnea, pneumonia, upper respiratory infections

**SKIN:** Diaphoresis, maculopapular rash, pruritus, pustular rash, rash, urticaria, vesiculobullous rash

**Other:** **Angioedema**, **hypokalemia**, **hypophosphatemia**, immune reconstitution syndrome, **lactic acidosis**, lipodystrophy, pain, weight loss

## Nursing Considerations

- Know that HIV-1 antibody testing should be done on all HBV-infected patients before initiating therapy with tenofovir, to avoid the development of HIV-1 resistance.
- Obtain an estimated creatinine clearance, serum creatinine, urine glucose, and urine protein in all patients prior to initiating tenofovir therapy and periodically throughout, as ordered, because drug is principally eliminated by the kidneys. Renal impairment may occur, which may become severe in patients with chronic kidney disease. Also know that patient's serum phosphorus level should be assessed before and during therapy. Report at any time throughout therapy patient complaints of bone, extremity, or muscle pain or weakness or if patient sustains a fracture, as these may be manifestations of proximal renal tubulopathy and require a prompt evaluation of renal function.
- Be aware that tenofovir should not be used in combination with any other drug containing tenofovir or adefovir dipivoxil. Also know that tenofovir should not be administered with nephrotoxic agents such as high-dose or multiple NSAIDs, because of increased risk of renal dysfunction.
- Measure oral powder using only the supplied dosing scoop. Mix with 2 to 4 ounces of soft food not requiring chewing, such as applesauce, baby food, or yogurt. Administer mixture immediately to avoid a bitter taste. Do not mix powder in a liquid because the powder may float on top of the liquid even after stirring.

**WARNING** Monitor patient being treated for hepatitis B upon discontinuation of tenofovir for several months, because severe acute exacerbations of hepatitis have occurred when drug has been stopped. Monitoring should include not only an assessment for signs and

symptoms of hepatitis, but also laboratory studies such as liver enzymes, as ordered.

- Notify prescriber if patient develops a fracture and/or muscular pain or weakness, persistent or worsening bone pain, or pain in extremities, as these may be signs and symptoms of proximal renal tubulopathy and require further evaluation.

**WARNING** Monitor patient for signs and symptoms, as well as laboratory findings, of lactic acidosis or pronounced hepatotoxicity that may develop with tenofovir therapy. Know that hepatomegaly and steatosis may occur even in the absence of marked transaminase elevations.

- Be aware that patients who have a history of pathologic bone fracture or other risk factors for bone loss or osteoporosis should be assessed regularly for bone density loss. Patient may benefit from calcium and vitamin D supplementation.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including tenofovir. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

## PATIENT TEACHING

- Instruct patient to take tenofovir exactly as prescribed and to avoid missing doses. If a dose is missed, tell patient to take the dose as soon as she remembers it, but not to double the dose. Warn patient not to discontinue the drug without consulting prescriber.
- Remind patient or caregiver measuring oral powder to use only the supplied dosing scoop, to ensure an accurate dose. Tell him to mix with 2 to 4 ounces of soft food not requiring chewing, such as applesauce, baby food, or yogurt, and to take mixture immediately to avoid a bitter taste. Tell patient not to mix powder in a liquid.
- Inform patient that bone density scanning may be ordered during tenofovir therapy.

- Tell patient to avoid high-dose or multiple NSAIDs while taking tenofovir, because of the risk of renal dysfunction.
- Caution patient to report any persistent, severe, or unusual signs and symptoms, including infection, to prescriber.
- Tell patient to inform all prescribers of tenofovir therapy, as other drugs containing tenofovir should not be prescribed during therapy.
- Tell woman of childbearing age to notify prescriber if pregnancy occurs. Encourage her to enroll in the Antiretroviral Pregnancy Registry by calling 1-800-258-4263.
- Inform mothers not to breastfeed during tenofovir therapy.

**WARNING** Inform patients who are discontinuing tenofovir after being treated for hepatitis B virus to seek medical attention if signs and symptoms of hepatitis reappear. This is because severe acute exacerbations of hepatitis may occur for many months after drug has been discontinued.

## terazosin hydrochloride

### Class and Category

*Pharmacologic class:* Alpha adrenergic blocker

*Therapeutic class:* Antihypertensive, benign prostatic hyperplasia (BPH) agent

*Pregnancy category:* C

### Indications and Dosages

➤ *To manage hypertension*

### CAPSULES

**Adults.** *Initial:* 1 mg at bedtime. *Maintenance:* 1 to 5 mg daily as a single dose or in divided doses every 12 hr. *Maximum:* 20 mg daily.

➤ *To treat symptomatic BPH*

## CAPSULES

**Adults.** *Initial:* 1 mg at bedtime, increased in increments to 2, 5, and then 10 mg, as needed, based on symptom improvement and urine flow rate. *Maintenance:* 10 mg daily as a single dose or in divided doses every 12 hr. *Maximum:* 20 mg daily.

Route	Onset	Peak	Duration
P.O.	15 min	2-3 hr	24 hr

## Mechanism of Action

Blocks postsynaptic  $\alpha_1$ -adrenergic receptors in many tissues, including the bladder neck, the prostate and vascular smooth muscle. This action promotes vasodilation, which reduces blood pressure and improves urine flow.

## Contraindications

Hypersensitivity to terazosin, other quinazolines, or their components

## Interactions

### DRUGS

*clonidine:* Possibly decreased clonidine effects

*diuretics, other antihypertensives:* Additive hypotensive effect

*dopamine*: Risk of decreased terazosin effects and antagonized vasoconstrictive effect of dopamine (in high doses)

*epinephrine*: Risk of decreased terazosin effects, possibly severe hypotension and tachycardia

*indomethacin, other NSAIDs*: Altered terazosin effects related to sodium and fluid retention

*methoxamine*: Decreased vasopressor effects, and shortened duration of action of these drugs

*phosphodiesterase-5 inhibitors, verapamil*: Additive blood pressure-lowering effects and symptomatic hypotension

*sympathomimetics*: Decreased terazosin effects

## Adverse Reactions

**CNS**: Asthenia, dizziness, headache, lethargy, nervousness, paresthesia, somnolence, syncope, vertigo

**CV**: Chest pain, **hypotension**, orthostatic hypotension, palpitations, peripheral edema, sinus tachycardia

**EENT**: Blurred vision, dry mouth, intraoperative floppy iris syndrome, nasal congestion, sinusitis

**GI**: Constipation, diarrhea, nausea, vomiting

**MS**: Arthralgia, back pain

**Other**: Flu-like symptoms, weight gain

## Nursing Considerations

- Be aware that prostate cancer should be ruled out before giving terazosin for BPH.
- Expect prescriber to reduce terazosin dosage if a diuretic or another antihypertensive is added to patient's regimen.
- Monitor blood pressure 2 to 3 hours after initial dose because of possible first-dose hypotension and again after 24 hours to evaluate patient's response.

- If patient requires administration by feeding tube, place capsule in 60 ml of warm tap water. Stir until capsule shell dissolves and liquid contents are released into water (5 to 10 minutes).
- Be aware that elderly patients may have exaggerated hypotension and other adverse reactions.

## PATIENT TEACHING

- Instruct patient to take terazosin at the same time each night.
- Explain possible first-dose hypotension. Advise patient to change position and rise slowly to prevent syncope early in therapy. Suggest lying down or sitting if dizziness or light-headedness occurs.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to notify prescriber if she misses several doses in a row; caution her against resuming therapy at previous dose.
- Inform patient that drug may take 2 to 6 weeks to improve urinary hesitancy.
- Advise patient to avoid alcohol use, excessive exercise, exposure to hot weather, or prolonged standing, because these activities can worsen orthostatic hypotension.
- Emphasize the importance of regular follow-up visits with prescriber to evaluate patient's response to drug.

**terbinafine hydrochloride**

**Lamisil**

## Class and Category

*Pharmacologic class:* Allylamine derivative

*Therapeutic class:* Antifungal

*Pregnancy category: B*

## Indications and Dosages

- *To treat onychomycosis of fingernails and toenails due to dermatophytes*

### **TABLETS**

**Adults and adolescents.** 250 mg once daily for 6 wk for fingernail onychomycosis and 12 wk for toenail onychomycosis.

- *To treat tinea capitis*

### **ORAL GRANULES**

**Adults and children age 4 and over weighing more than 35 kg (77 lb).** 250 mg once daily for 6 wk.

**Children age 4 and over weighing 25 kg (55 lb) to 35 kg (77 lb).** 187.5 mg once daily for 6 wk.

**Children age 4 and over weighing less than 25 kg (55 lb).** 125 mg once daily for 6 wk.

## Mechanism of Action

Inhibits the conversion of squalene mono-oxygenase to squalene epoxidase, a key enzyme in fungal biosynthesis. The resulting squalene accumulation weakens cell membranes and creates a deficiency of ergosterol, the fungal membrane component necessary for normal fungal growth.

## Contraindications

Active or chronic liver disease, hypersensitivity to terbinafine or its components

## Interactions

### DRUGS

*beta blockers, class 1C antiarrhythmics such as flecainide and propafenone, MAO inhibitors (type B), selective serotonin reuptake inhibitors, tricyclic antidepressants:*

Possibly increased blood levels of these drugs

*cimetidine, other hepatic enzyme inhibitors:* Significantly decreased terbinafine clearance, possibly increased adverse reactions

*cyclosporine:* Increased clearance of cyclosporine and decreased effectiveness of cyclosporine

*CYP2C and CYP3A4 inhibitors such as amiodarone and ketoconazole:* Possibly increased systemic exposure of terbinafine

*hepatotoxic drugs:* Increased risk of hepatotoxicity

*rifampin:* Increased clearance and decreased effectiveness of terbinafine

*warfarin:* Altered prothrombin time

### FOODS

*caffeine:* Decreased caffeine clearance

### ACTIVITIES

*alcohol use:* Increased risk of severe hepatitis

## Adverse Reactions

**CNS:** Anxiety, depression, fatigue, fever, headache, hypoesthesia, malaise, paresthesia, vertigo

**CV:** Myocarditis, pericarditis, thrombotic microangiopathy, vasculitis

**EENT:** Hearing impairment, loss of smell, reduced visual acuity, taste loss or perversion (possibly severe), tinnitus, visual field defect

**GI:** Abdominal pain, anorexia, cholestasis, diarrhea, elevated liver enzymes, flatulence, hepatic failure, hepatitis, hepatotoxicity, indigestion, jaundice, nausea, pancreatitis, vomiting

**GU:** Hemolytic uremic syndrome, nephritis

**HEME:** Agranulocytosis, anemia, neutropenia (severe), pancytopenia, thrombocytopenia, thrombotic thrombocytopenic purpura

**MS:** Arthralgia, myalgia, rhabdomyolysis

**RESP:** Pneumonitis

**SKIN:** Acute generalized exanthematous pustulosis, alopecia, bullous dermatitis, cutaneous lupus erythematosus, erythema multiforme, exacerbation of psoriasis, exfoliative dermatitis, photosensitivity, psoriasiform eruptions, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis, angioedema, drug reaction with eosinophilia and systemic symptoms (DRESS), elevated blood creatine phosphokinase, influenza-like illness, serum sickness-like reaction, systemic lupus erythematosus

## Nursing Considerations

- Know that because terbinafine has been linked to serious adverse hepatic effects, expect to send nail specimens for laboratory testing to confirm onychomycosis before starting therapy. Also expect to check liver enzymes, as ordered, prior to starting therapy.
- Ensure that patient's liver enzymes have been checked before terbinafine therapy is begun, to rule out preexisting liver disease. Expect to monitor

liver enzymes regularly throughout therapy if baseline enzymes are normal.

- Sprinkle entire contents of each packet of oral granules on a spoonful of nonacidic food such as mashed potatoes or pudding and have patient swallow contents in its entirety.
- Administer oral granules by sprinkling the contents of each packet on a spoonful of pudding or other soft, nonacidic food such as mashed potatoes and have patient swallow the entire spoonful without chewing. Do not use applesauce or fruit-based foods. If patient is taking 2 packets of oral granules, both packets may be sprinkled on one spoonful of food or each packet may be sprinkled on a separate spoonful. Give drug with food.
- Monitor patient for hepatic failure (anorexia, dark urine, fatigue, jaundice, nausea, pale stools, right upper abdominal pain, and vomiting). Know that periodic monitoring of liver enzymes should be done throughout therapy because hepatotoxicity may also occur in patients without preexisting liver disease. Expect to stop drug and obtain liver enzyme tests if these problems develop.

**WARNING** Monitor patient for serious hypersensitivity or skin reactions such as Stevens–Johnson syndrome or drug reaction with eosinophilia and systemic symptoms (DRESS) syndrome. Know that in addition to skin abnormalities such as rash and urticaria, DRESS may also involve one or more organs. If hypersensitivity reactions persist or progress, notify prescriber and expect drug to be discontinued.

- Monitor patient's complete blood count, as ordered. Know that thrombotic microangiopathy has occurred with terbinafine use and can be life-threatening. Notify prescriber promptly of any abnormalities, especially unexplained anemia and thrombocytopenia. If thrombotic microangiopathy is confirmed, expect drug to be discontinued.

## **PATIENT TEACHING**

- Tell patient or parents to sprinkle each packet of oral granules onto a spoonful of nonacidic food such as mashed potatoes or pudding and have patient swallow it in its entirety.

- Emphasize the need to complete the full course of terbinafine therapy to prevent relapse of infection.
- Instruct patient prescribed oral granules to sprinkle the contents of each packet on a spoonful of pudding or other soft, nonacidic food such as mashed potatoes and swallow the entire spoonful without chewing. Caution patient not to use applesauce or fruit-based foods. If patient is taking 2 packets of oral granules, tell him that both packets may be sprinkled on one spoonful or each packet may be sprinkled on a separate spoonful. Stress importance of taking drug with food.
- Discourage consumption of alcohol during therapy.
- Tell patient to contact prescriber if onychomycosis doesn't improve in a few weeks.
- Instruct patient to notify prescriber if he develops persistent anorexia, dark urine, fatigue, jaundice, nausea, pale stools, or right upper abdominal pain. Stress importance of stopping terbinafine therapy immediately if any of these symptoms occur.
- Instruct patient to avoid direct sunlight or UV light and to wear sunscreen when outdoors.
- Tell patient to watch for skin reactions, such as hives, itching, or rash suggestive of a hypersensitivity reaction. If present, tell patient to notify prescriber.
- Instruct patient to inform prescriber of any unexplained bleeding or bruising that may occur.
- Advise patient to alert prescriber if loss or perversion of taste occurs and becomes severe enough to cause anxiety, depression, or weight loss.

## terbutaline sulfate

**Brethaire, Brethine, Bricanyl,  
Bricanyl Turbuhaler (CAN)**

### **Class and Category**

*Pharmacologic class:* Beta adrenergic receptor agonist

*Therapeutic class:* Bronchodilator

*Pregnancy category:* B

## Indications and Dosages

- *To prevent or reverse bronchospasm from asthma, bronchitis, or emphysema*

### **TABLETS (BRETHINE, BRICANYL)**

**Adults and adolescents age 15 and over.** 2.5 to 5 mg three times a day at 6-hr intervals while awake. *Maximum:* 15 mg daily.

**Children ages 12 to 15.** 2.5 mg three times a day at 6-hr intervals while awake. *Maximum:* 7.5 mg daily.

**Children ages 6 to 11.** 50 to 75 mcg/kg three times a day at 6-hr intervals while awake. *Maximum:* 150 mcg/kg/dose or 5 mg daily.

### **SUBCUTANEOUS INJECTION (BRICANYL)**

**Adults and children age 12 and over.** *Initial:* 0.25 mg, repeated in 15 to 30 min as needed. *Maximum:* 0.5 mg/4-hr period.

**Children ages 6 to 12.** 5 to 10 mcg (0.005 to 0.01 mg)/kg every 15 to 20 min, up to three doses. *Maximum:* 400 mcg (0.4 mg)/dose.

### **INHALATION AEROSOL (BRETHAIRE)**

**Adults and children.** 2 inhalations (400 mcg) every 4 to 6 hr, as needed.

### **INHALATION AEROSOL (BRICANYL TURBUHALER)**

**Adults and children.** 1 inhalation (500 mcg), repeated after 5 min, as needed. *Maximum:* 6 inhalations daily.

Route	Onset	Peak	Duration
P.O.	30-90 min	2-3 hr	4-8 hr
SubQ	15-30 min	30-60 min	1.5-4 hr
Inhalation	In 5 min	30-90 min	3-6 hr

## Mechanism of Action

Stimulates beta<sub>2</sub>-adrenergic receptors in the lungs, which is believed to increase production of cAMP. The increased cAMP level relaxes bronchial smooth muscles, thereby increasing bronchial airflow and relieving bronchospasm.

## Contraindications

Hypersensitivity to terbutaline, other sympathomimetic amines, or their components

## Interactions

### DRUGS

*antihypertensives, diuretics:* Decreased antihypertensive effect

*beta blockers:* Mutual inhibition of therapeutic effects, increased risk of bronchospasm

*CNS stimulants:* Additive CNS stimulation, possibly resulting in adverse effects

*digoxin:* Increased risk of arrhythmias, possibly digitalis toxicity

*halogenated anesthetics:* Possibly ventricular arrhythmias

*MAO inhibitors:* Possibly potentiated action of terbutaline; headache, hyperpyrexia, hypertension, possible hypertensive crisis

*tricyclic antidepressants:* Possibly potentiated action of terbutaline

*nitrates:* Decreased effectiveness of nitrates

*ritodrine:* Increased effects of either drug and potential for adverse effects

*sympathomimetics:* Increased CNS stimulation and risk of adverse cardiovascular effects, including prolonged QT interval

*thyroid hormones:* Increased effects of either drug, risk of coronary insufficiency in patients with coronary artery disease

*xanthines (theophylline):* Increased CNS stimulation and other additive toxic effects

## **FOODS**

*caffeine:* Increased CNS stimulation and other additive toxic effects

## **Adverse Reactions**

**CNS:** Anxiety, dizziness, drowsiness, headache, insomnia, light-headedness, nervousness, restlessness, tremor, weakness

**CV:** Chest pain, **irregular heartbeat**, palpitations, tachycardia

**EENT:** Dry mouth, taste perversion

**ENDO:** Hyperglycemia

**GI:** Heartburn, nausea, vomiting

**MS:** Muscle spasms

**RESP:** Dyspnea

**SKIN:** Diaphoresis, flushing, rash

# Nursing Considerations

- Use terbutaline cautiously in patients with cardiovascular disease because drug can adversely affect cardiovascular function. Monitor patient's heart rate and rhythm and blood pressure, and assess for chest pain.
- For subcutaneous use, inject into lateral deltoid area.
- Assess patient's respiratory rate, depth, and quality; oxygen saturation; and activity tolerance at regular intervals because continuous use of beta<sub>2</sub>-agonists for 12 months or longer accelerates the decline in pulmonary function.

## PATIENT TEACHING

- Teach patient how to use terbutaline aerosol inhaler or give subcutaneous injection, as needed.
- Instruct patient not to increase dose or frequency without consulting prescriber.
- Urge patient to seek immediate medical attention if symptoms worsen.
- Inform patient that she may experience transient nervousness or tremors during terbutaline therapy.

**teriflunomide**

**Aubagio**

## Class and Category

*Pharmacologic class:* Pyrimidine synthesis inhibitor

*Therapeutic class:* Immunomodulator

*Pregnancy category:* X

# Indications and Dosages

➤ *To treat relapsing forms of multiple sclerosis*

## **TABLETS**

**Adults.** 7 or 14 mg once daily.

## **Mechanism of Action**

Inhibits dihydroorotate dehydrogenase, a mitochondrial enzyme involved in de novo pyrimidine synthesis to possibly reduce the number of activated lymphocytes in the central nervous system responsible for the signs and symptoms of multiple sclerosis.

## **Contraindications**

Concurrent therapy with leflunomide; hypersensitivity to teriflunomide, leflunomide, or their components; pregnancy; severe hepatic impairment; women of childbearing age not using reliable contraception

## **Interactions**

### **DRUGS**

*alosetron, caffeine, duloxetine, theophylline, tizanidine:*  
Reduced effectiveness of these drugs

*ethinylestradiol, levonorgestrel:* Increased risk of adverse reactions related to these drugs

*paclitaxel, pioglitazone, repaglinide, rosiglitazone:* Possibly increased exposure of these drugs with potential for leading to adverse effects

*warfarin:* Decreased peak international normalized ratio

# Adverse Reactions

**CNS:** Anxiety, burning sensation, headache, paresthesia, peripheral neuropathy, sciatica

**CV:** Hypertension, palpitations

**EENT:** Blurred vision, conjunctivitis, oral herpes, sinusitis, toothache

**GI:** Abdominal distention, diarrhea, elevated liver enzymes, gastroenteritis, **hepatic dysfunction or failure**, nausea, **pancreatitis**, upper abdominal pain

**GU:** **Acute renal failure**, acute uric acid nephropathy, cystitis, elevated serum creatinine levels

**HEME:** **Leukopenia**, **neutropenia**, **thrombocytopenia**

**MS:** Manifestation of carpal tunnel syndrome, musculoskeletal pain, myalgia

**RESP:** **Acute interstitial pneumonitis**, bronchitis, dyspnea, **interstitial lung disease**, upper respiratory infection

**SKIN:** Acne, alopecia, pruritus, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, flu-like symptoms, **hyperkalemia**, onset of seasonal allergies, weight loss

# Nursing Considerations

- Know that teriflunomide isn't recommended for patients with bone marrow dysplasia, severe immunodeficiency, or severe, uncontrolled infections because of its immunosuppressant effect. It is also not recommended for patients with liver disease or those with a serum alanine aminotransferase level greater than two times the upper level normal prior to initiation of therapy because drug may worsen liver dysfunction.
- Obtain a pregnancy test on all women of childbearing age, as ordered, prior to starting teriflunomide therapy. Know that drug should not be started if pregnancy is suspected or confirmed and in women who refuse to use a reliable contraceptive.

- Use cautiously in patients who are over 60 years of age, patients with diabetes, or in patients taking concomitant neurotoxic drugs because of an increased risk of developing peripheral neuropathy. If peripheral neuropathy occurs during teriflunomide therapy, notify prescriber and expect drug to be discontinued and possibly cholestyramine washout ordered.
- Test patient for latent tuberculosis before starting leflunomide, as ordered. If positive, expect standard medical treatment to be given before teriflunomide therapy starts.
- Obtain baseline blood pressure before starting teriflunomide, and monitor periodically thereafter because drug may cause hypertension.
- Assess liver enzyme (ALT and AST) levels at start of therapy, monthly during first 6 months, and if stable, every 6 to 8 weeks thereafter, as ordered. If levels become elevated greater than threefold upper level normal, notify prescriber and expect teriflunomide therapy to be withheld until underlying cause is determined. If the elevation is thought to be teriflunomide induced, expect to start cholestyramine washout, as ordered, and monitor liver test weekly until normalized. If another cause is found for the elevation, expect to resume teriflunomide therapy.
- Ensure that a complete CBC has been done within the past 6 months prior to starting teriflunomide therapy to use as a baseline. Repeat CBC, as ordered, thereafter if signs and symptoms of bone marrow suppression occur.
- Notify prescriber if patient develops a serious infection or skin condition because drug may need to be interrupted and charcoal or cholestyramine given to eliminate drug rapidly.

**WARNING** Monitor patient's respiratory function closely because drug may cause interstitial lung disease that could become life-threatening. If patient develops a cough and dyspnea, notify prescriber; drug may need to be stopped, and patient may need charcoal or cholestyramine to eliminate drug rapidly.

- Check patient's serum potassium level, as ordered, if symptoms of acute renal failure or hyperkalemia occur.

## **PATIENT TEACHING**

- Tell patient to report signs of respiratory dysfunction, such as cough and dyspnea.

**WARNING** Caution woman of childbearing potential not to become pregnant while taking drug because of the high risk of birth defects. Emphasize importance of using reliable forms of birth control and to notify prescriber immediately if pregnancy is suspected. Also advise men not wishing to father a child and their female partners to use effective contraception to minimize any possible risk to the fetus.

- Inform women to discuss breastfeeding with their prescriber, because they cannot breastfeed while taking teriflunomide.
- Advise patient to avoid live vaccines during teriflunomide therapy.
- Instruct patient to notify prescriber if she develops an infection or skin condition.
- Instruct patient to stop taking teriflunomide if he develops an allergic reaction, including difficulty breathing; itching or swelling of eyes, face, lips, throat, or tongue; fever, rash, or swollen glands; or signs of liver dysfunction such as darkened urine, fatigue, and yellow eyes or skin. In addition, patient should seek immediate medical attention.

## Mechanism of Action

Teriparatide, which contains recombinant PTH, stimulates new bone growth and increases bone density. In a patient with osteoporosis, bone density and mass are diminished by an imbalance between bone destruction and formation. Normally, osteoclasts break down and resorb bone, leaving behind a cavity in a section of bone. Then bone-building cells, called osteoblasts, line the walls of the cavity and stimulate new bone formation. PTH stimulates these actions by attaching to receptors on osteoclasts and osteoblasts,

as shown below. Teriparatide binds to cell-surface receptors on osteoblasts and preferentially stimulates osteoblastic over osteoclastic activity. Also, the drug increases the amount of circulating calcium available for bone formation by increasing the intestinal absorption of calcium and phosphate, thus enhancing the rate of calcium resorption from bone, increasing the reabsorption of calcium, and inhibiting the reabsorption of phosphate in the kidneys. These actions stimulate new bone formation and increase bone density to reduce osteoporotic bone changes.

# teriparatide

## Forteo

### Class and Category

*Pharmacologic class:* Recombinant human parathyroid hormone (PTH)

*Therapeutic class:* Antiosteoporotic

*Pregnancy category:* C

## Indications and Dosages

- *To treat osteoporosis in postmenopausal women and primary or hypogonadal osteoporosis in men at high risk for fracture; to treat men and women with glucocorticoid-induced osteoporosis at high risk for fracture*

## SUBCUTANEOUS INJECTION

**Adults.** 20 mcg daily for up to 2 yr.

Route	Onset	Peak	Duration
SubQ	2 hr	4–6 hr	16–24 hr

## Contraindications

Hypersensitivity to teriparatide or its components

## Interactions

### DRUGS

*digitalis glycosides:* Possibly increased risk of digitalis toxicity

## Adverse Reactions

**CNS:** Asthenia, depression, dizziness, headache, insomnia, paresthesia, syncope, vertigo

**CV:** Angina pectoris, chest pain, hypertension, transient orthostatic hypotension

**EENT:** Pharyngitis, rhinitis, taste perversion, tooth disorder

**ENDO:** Hypoparathyroidism

**GI:** Constipation, diarrhea, indigestion, vomiting

**MS:** Arthralgia, muscle cramps or spasms in back or leg, neck pain

**RESP:** Cough, dyspnea, pneumonia

**SKIN:** Diaphoresis, pruritus, rash, urticaria

**Other:** **Angioedema**, generalized pain, **hypercalcemia**, **hypocalcemia** injection-site reactions (erythema, localized bruising, minor bleeding, pain, pruritus, swelling)

## Nursing Considerations

**WARNING** Be aware that teriparatide shouldn't be used to treat patients at risk for osteosarcoma (such as those with Paget's disease or a metabolic bone disease other than osteoporosis), unexplained elevations of alkaline phosphatase, open epiphyses, or prior skeletal radiation or malignancy.

**WARNING** Be aware that patients with hypercalcemia shouldn't receive teriparatide because drug may worsen hypercalcemia.

- Use drug cautiously in patients with active or recent urolithiasis because drug could worsen this condition.
- Monitor patient closely for allergic reactions because teriparatide is a peptide agent.
- Monitor patient's blood calcium level, and notify prescriber of any elevation; in persistent hypercalcemia, the drug may have to be stopped.
- Monitor patient's blood pressure during the first several doses of drug therapy because of a risk of transient orthostatic hypotension. If this occurs, place patient in a reclining position and alert prescriber.

## PATIENT TEACHING

- Teach patient how to administer teriparatide by subcutaneous injection and how to properly use the delivery pen device and dispose of needles. Advise her not to share pen device with others.
- Inform patient that each delivery pen can be used for up to 28 days after the first injection but then should be discarded even if it still contains solution.
- Instruct patient to store the delivery pen in the refrigerator and to recap it when not in use to protect it from damage and light.
- Tell patient that delivery pen may be used immediately after removal from refrigerator and should be put back in refrigerator as soon as the injection is given.
- Instruct patient to inject drug into thigh or abdominal wall and to rotate injection sites.
- Caution patient to administer drug in a room where she can immediately sit or lie down if light-headedness or palpitations occur. Advise her to notify prescriber if these symptoms persist or worsen.
- Instruct patient to notify prescriber of persistent symptoms of hypercalcemia, such as nausea, vomiting, constipation, lethargy, and muscle weakness.
- Caution patient about potential developing osteosarcoma.

## tetracycline hydrochloride

### Class and Category

*Pharmacologic class:* Tetracycline

*Therapeutic class:* Antibiotic

*Pregnancy category:* D

### Indications and Dosages

- *To treat infections caused by gram-negative and gram-positive organisms*

## **CAPSULES**

**Adults.** 250 mg four times daily or 500 mg twice daily increased to 500 mg four times daily, as needed for severe infections or those not responding to lower doses.

**Children age 9 and over.** 25 to 50 mg/kg daily divided into four equal doses.

- *To treat moderate to severe acne vulgaris in patients requiring long-term treatment*

## **CAPSULES**

**Adults.** *Initial:* 1,000 mg daily in divided doses until improvement occurs (usually in 3 wk); then dosage reduced gradually. *Maintenance:* 125 to 500 mg daily, every other day, or intermittently.

- *To treat brucellosis caused by susceptible organisms*

## **CAPSULES**

**Adults.** 500 mg every 6 hr for 3 wk, given with 1 g of streptomycin I.M. every 12 hr in wk 1 and daily in wk 2.

- *To treat gonorrhea caused by *Neisseria gonorrhoeae**

## **CAPSULES**

**Adults.** 500 mg every 6 hr for 5 days.

- *To treat syphilis in patients allergic to penicillin*

## **CAPSULES**

**Adults.** 500 mg every 6 hr for 15 days (for early syphilis of less than 1 yr duration) or 30 days (for late syphilis with more than 1 yr duration except for neurosyphilis).

- *To treat uncomplicated endocervical, rectal, or urethral infections caused by Chlamydia trachomatis*

## **CAPSULES**

**Adults.** 500 mg four times a day for at least 7 days.

***DOSAGE ADJUSTMENT*** For patients with renal impairment, dosage reduced or time intervals extended between doses because of extended half-life.

## **Mechanism of Action**

Exerts a bacteriostatic effect against a wide variety of gram-negative and gram-positive organisms by passing through the bacterial lipid bilayer, where it binds reversibly to 30S ribosomal subunits. Bound tetracycline blocks the binding of aminoacyl transfer RNA to messenger RNA, thus inhibiting bacterial protein synthesis.

## **Contraindications**

Hypersensitivity to tetracycline or its components

## **Interactions**

### **DRUGS**

*aluminum-, calcium-, or magnesium-containing antacids; iron supplements (oral); magnesium-containing laxatives; magnesium salicylate; multivitamins (containing manganese or zinc salts); sodium bicarbonate:* Possibly impaired absorption of oral tetracycline and formation of nonabsorbable complexes  
*cholestyramine, colestipol:* Possibly impaired absorption of oral tetracycline

*digoxin*: Possibly increased digoxin level  
*methoxyflurane*: Possibly nephrotoxicity  
*oral contraceptives (containing estrogen)*: Possibly reduced contraceptive reliability and increased risk of breakthrough bleeding (with long-term tetracycline use)  
*penicillins*: Possibly decreased bactericidal effect of penicillins  
*vitamin A*: Possibly benign intracranial hypertension

## FOODS

*dairy products and other foods*: Possibly impaired absorption of oral tetracycline

## Adverse Reactions

**CNS**: Dizziness, light-headedness, unsteadiness

**EENT**: Darkened or discolored tongue, enamel hypoplasia, oral candidiasis, tooth discoloration (in children)

**GI**: Abdominal pain, diarrhea, **hepatotoxicity**, nausea, rectal candidiasis, vomiting

**GU**: Vaginal candidiasis

**SKIN**: Photosensitivity

## Nursing Considerations

- Avoid giving tetracycline to children age 8 and under because drug may cause permanent brown or yellow tooth discoloration and enamel hypoplasia.
- Be aware that enamel hypoplasia and tooth discoloration may occur in breastfed infants, along with inhibition of linear skeletal growth, oral and vaginal candidiasis, and photosensitivity.
- Know that to reduce the risk of esophageal irritation or ulceration, bedtime dosing of tetracycline should be avoided for patient with esophageal obstruction or compression.

- Assess for photosensitivity, which can develop within a few minutes or up to several hours after exposure to sunlight or other ultraviolet (UV) light. Effects may last for 1 to 2 days after discontinuation of drug.
- Be aware that citric acid in tetracycline preparations may accelerate drug deterioration and that using outdated drug may cause Fanconi's syndrome, characterized by multiple defects in renal tubular function. Symptoms include acidosis, bicarbonate wasting, glycosuria, hypokalemia, osteomalacia, and phosphaturia.

## **PATIENT TEACHING**

- Instruct patient to take oral tetracycline at least 1 hour before meals or 2 hours after meals because dairy products and some foods may interfere with absorption.
- Advise patient to take each dose with a full glass of water while in an upright position to avoid esophageal or GI irritation.
- Advise patient to avoid taking other drugs, including OTC antacids and other preparations, within 3 hours of oral tetracycline.
- Urge patient to complete entire course of tetracycline therapy even if she feels better.
- Caution her to avoid direct sunlight or UV light and to wear sunscreen when outdoors.
- Advise women who use oral contraceptives containing estrogen to use another method of contraception while taking tetracycline because contraceptives may be less effective. Tell patient to notify prescriber immediately if pregnancy is known or suspected.
- Emphasize the need to discard outdated tetracycline because of the risk of toxic effects.
- Encourage patient to take safety precautions if she experiences dizziness or other adverse CNS reactions.

**tiagabine hydrochloride**

**Gabitril**

## Class and Category

*Pharmacologic class:* Gamma aminobutyric acid (GABA) reuptake inhibitor

*Therapeutic class:* Anticonvulsant

*Pregnancy category:* C

## Indications and Dosages

► *As adjunct to treat partial seizures*

### TABLETS

**Adults already taking enzyme-inducing antiepileptic drugs.** *Initial:* 4 mg daily; increased by 4 to 8 mg/wk until desired response occurs given in two to four divided doses daily. *Usual:* 32 to 56 mg daily. *Maximum:* 56 mg daily in two to four divided doses.

**Children ages 12 to 18 already taking enzyme-inducing antiepileptic drugs.** *Initial:* 4 mg daily for 1 wk, then increased to 8 mg, followed a wk later by increases of 8 mg/wk until desired response occurs and given in two to four divided doses daily. *Maximum:* 32 mg daily in two to four divided doses.

***DOSAGE ADJUSTMENT*** For patients taking only non-enzyme-inducing antiepileptic drugs, dosage reduced and possibly a slower titration schedule required. For patients with impaired hepatic function, dosage individualized and reduced, or interval extended if needed.

## Mechanism of Action

Appears to inhibit neuronal and glial uptake of gamma-aminobutyric acid (GABA), the major inhibitory neurotransmitter in the CNS. Tiagabine makes more GABA

available in the CNS to open chloride channels in postsynaptic membranes, thereby leading to membrane hyperpolarization and preventing transmission of nerve impulses.

## Contraindications

Hypersensitivity to tiagabine or its components

## Interactions

### DRUGS

*benzodiazepines, CNS depressants*: Possibly additive CNS depression

*carbamazepine, phenobarbital, phenytoin*: Possibly decreased tiagabine effectiveness

*St. John's wort*: Possibly enhanced metabolism of tiagabine

### ACTIVITIES

*alcohol use*: Possibly additive CNS depression

## Adverse Reactions

**CNS**: Amnesia, anxiety, asthenia, ataxia, confusion, depression, dizziness, drowsiness, EEG abnormalities, hostility, impaired cognition, insomnia, light-headedness, paresthesia, **seizures, status epilepticus, suicidal ideation**, tremor, weakness

**EENT**: Blurred vision, pharyngitis, stomatitis

**GI**: Abdominal pain, diarrhea, increased appetite, nausea, vomiting

**GU**: UTI

**MS**: Dysarthria

**SKIN:** Bullous dermatitis, ecchymosis, rash

## Nursing Considerations

- Give tiagabine with food.

**WARNING** Expect to taper dosage gradually, as prescribed, because stopping drug abruptly may increase seizure frequency.

- Take seizure precautions because tiagabine has caused seizures and status epilepticus in patients with no history of seizures.
- Watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and report concerns at once.

## PATIENT TEACHING

- Instruct patient to take drug with food.
- Advise patient to avoid hazardous activities until drug's CNS effects are known. Also urge her to avoid alcohol use.
- Inform patient who takes a CNS depressant, that drug may increase depressant effect.
- Instruct patient not to stop taking tiagabine abruptly. Explain that prescriber usually tapers dosage over 4 weeks to reduce the risk of withdrawal seizures.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns immediately.
- Encourage woman who becomes pregnant while taking tiagabine to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy.

# ticagrelor

## Brilinta

### Class and Category

*Pharmacologic class:* P2Y<sub>12</sub> platelet inhibitor

*Therapeutic class:* Antiplatelet

*Pregnancy category:* C

### Indications and Dosages

- *To reduce the rate of thrombotic cardiovascular events such as cardiovascular death, myocardial infarction, and stroke in patients with acute coronary syndrome (ACS) or history of myocardial infarction; reduce rate of stent thrombosis in patients who have been stented for treatment of ACS*

### **TABLETS**

**Adults.** *Initial:* 180 mg as a loading dose followed by 90 mg twice daily for 1 yr, then 60 mg twice daily.

### Mechanism of Action

Reversibly interacts with the platelet P2Y<sub>12</sub> ADP-receptor to prevent platelet activation.

### Contraindications

Active bleeding, history of intracranial hemorrhage, hypersensitivity to ticagrelor or its components, severe hepatic impairment

## Interactions

### DRUGS

*aspirin (daily doses above 100 mg):* Reduced effectiveness of ticagrelor

*CYP3A inducers such as carbamazepine, dexamethasone, phenobarbital, phenytoin, rifampin:* Elevated ticagrelor levels and risk of adverse effects

*CYP3A inhibitors such as atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, voriconazole:* Substantially reduced blood ticagrelor levels and effectiveness

*digoxin:* Altered blood digoxin levels

*lovastatin, simvastatin:* Increased serum levels of these drugs

*opioids:* Delayed or reduced absorption of ticagrelor

## Adverse Reactions

**CNS:** Dizziness, fatigue, headache, **intracranial bleeding**

**CV:** **Atrial fibrillation, bradycardia including AV block, chest pain, hypertension, hypotension (may be severe), intracardiac bleed with cardiac tamponade**

**EENT:** Epistaxis, intraocular bleeding with permanent vision loss

**ENDO:** Gynecomastia

**GI:** Diarrhea, nausea

**GU:** Elevated serum creatinine level

**HEME:** Minor or **major bleeding**

**MS:** Back or noncardiac chest pain

**RESP:** Cough, dyspnea

**SKIN:** Bruising, rash

**Other:** **Angioedema**, elevated uric acid, **hypovolemic shock**

## Nursing Considerations

- Be aware that ticagrelor shouldn't be given to patients with active pathological bleeding or who have a history of intracranial hemorrhage. It should also not be started in patients who are undergoing urgent coronary artery bypass graft (CABG) surgery or who have severe hepatic impairment.
- Know that patients with a history of bradycardia-related syncope not protected by a pacemaker, second or third AV block, or sick sinus syndrome may be at a higher risk of developing bradyarrhythmias with ticagrelor.
- Be aware that aspirin is used with ticagrelor therapy. Expect to administer 325 mg of aspirin initially followed by a maintenance dose of aspirin of 75 to 100 mg daily. Know that a patient who has already received a loading dose of clopidogrel may be started on ticagrelor therapy immediately.
- Be prepared to crush tablets and mix with water for patients who are unable to swallow tablets whole. Know that the mixture can also be administered via a nasogastric tube.
- Monitor patient closely for bleeding tendencies. Know that risk of bleeding increases with ticagrelor use in older patients as well as patients with a history of bleeding disorders or performance of percutaneous invasive procedures. Risk of bleeding also increases with concomitant use of drugs such as anticoagulant and fibrinolytic therapy, chronic use of nonsteroidal anti-inflammatory drugs, and higher doses of aspirin.
- Be prepared to discontinue ticagrelor therapy, as ordered, 5 days before surgery, if possible.
- Be suspicious of bleeding in a patient who becomes hypotensive and has recently undergone coronary angiography, CABG, PCI, or other surgical procedures, even if the patient does not have any signs of bleeding. Notify prescriber immediately if patient becomes hypotensive, and expect to provide supportive care. Be aware that attempts to manage bleeding should be made without discontinuing drug, if possible, because stopping ticagrelor increases risk of subsequent cardiovascular events.

- Monitor patient for dyspnea that may occur with ticagrelor therapy. If dyspnea is determined to be caused by the drug, expect to continue therapy as no specific treatment is needed and often resolves on its own.
- Avoid abrupt interruption of ticagrelor therapy because doing so increases the risk of myocardial infarction, stent thrombosis, and death.

## PATIENT TEACHING

- Warn patient not to discontinue ticagrelor therapy abruptly because of increased risk of life-threatening adverse effects.
- Advise patient unable to swallow the tablet whole to crush it and mix with water immediately before taking the drug.
- Advise patient to seek immediate emergency care if bleeding occurs and is serious.
- Instruct patient to take bleeding precautions such as avoiding the use of a razor and brushing teeth with a soft-bristled toothbrush.
- Tell patient to alert all prescribers of ticagrelor therapy.

**tildrakizumab-asmn**

**Ilumya**

## Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Immunomodulator

*Pregnancy category:* Not classified

## Indications and Dosages

- *To treat moderate to severe plaque psoriasis in patients who are candidates for systemic therapy or phototherapy*

## **SUBCUTANEOUS INJECTION**

**Adults.** 100 mg followed by 100 mg in 4 wk and then 100 mg every 12 wk thereafter.

## **Mechanism of Action**

Selectively binds to the p19 subunit of IL-23 and inhibits its interaction with the IL-23 receptor to inhibit the release of proinflammatory chemokines and cytokines, which reduces inflammation.

## **Contraindications**

Hypersensitivity to tildrakizumab-asmn or its components

## **Interactions**

### **DRUGS**

*live vaccines:* Increased risk of infection from live vaccine

## **Adverse Reactions**

**GI:** Diarrhea

**RESP:** Upper respiratory infections

**SKIN:** Urticaria

**Other:** **Angioedema**, antibody formation to tildrakizumab-asmn, injection-site reactions (bruising, edema, erythema, hematoma, hemorrhage, inflammation, pain, pruritus, swelling)

# Nursing Considerations

- Ensure that patient has been evaluated for tuberculosis prior to start of tildrakizumab-asmn therapy. Know that drug should not be given to patients with active tuberculosis. Know that patients with a past history of active or latent tuberculosis in whom an adequate course of treatment cannot be confirmed may need antituberculosis treatment before tildrakizumab-asmn is given.
- Know that tildrakizumab-asmn should not be given to patient with a serious infection until the infection resolves or is adequately treated.
- Check patient's immunization history to ensure that patient is current on immunizations before tildrakizumab-asmn therapy is begun. Do not administer a live vaccine while patient is taking tildrakizumab-asmn because of risk of infection.
- Remove tildrakizumab-asmn from refrigerator and let prefilled syringe sit, in the carton with lid closed, at room temperature for 30 minutes. Follow instructions on carton to remove syringe correctly, and remove only when ready to inject. Do not pull off needle cover until ready to inject. Inspect syringe contents. Solution should appear clear to slightly opalescent, colorless to slightly yellow. Air bubbles may be present, but there is no need to remove them.
- Pull needle cover straight off (do not twist) and discard. Inject drug subcutaneously into abdomen, thighs, or upper arm by pushing down the blue plunger until it can go no further. Remove needle from the skin entirely before letting go of the blue plunger. After the blue plunger is released, the safety lock will draw the needle inside the needle guard. If a dose is missed, administer the dose as soon as possible and then resume dosing at the regularly scheduled interval.

**WARNING** Monitor patient for angioedema and urticaria. If present, notify prescriber, expect drug to be discontinued, and provide supportive care, as ordered.

- Monitor patient for infections, especially respiratory infections. If patient develops a serious infection or is not responding to standard treatment for an infection, alert prescriber, as drug may have to be discontinued.

## PATIENT TEACHING

- Inform patient that tidrakizumab-asmn will be given by a health professional. Stress importance of keeping appointments for drug administration.
- Instruct patient to seek immediate medical attention if she experiences any serious allergic reactions after drug has been administered.
- Review signs and symptoms of infection with patient and tell patient to notify prescriber if present.

## timolol maleate

**Apo-Timol (CAN),  
Novo-Timol (CAN)**

### Class and Category

*Pharmacologic class:* Beta blocker

*Therapeutic class:* Antihypertensive, MI prophylactic, vascular headache prophylactic

*Pregnancy category:* C

### Indications and Dosages

➤ *To manage hypertension*

#### **TABLETS**

**Adults.** *Initial:* 10 mg twice daily, increased every wk as prescribed. *Maintenance:* 20 to 40 mg daily in divided doses. *Maximum:* 60 mg daily.

➤ *To provide long-term prophylaxis after MI*

## TABLETS

**Adults.** 10 mg twice daily, beginning 1 to 4 wk after MI and continuing for at least 2 yr.

➤ *To prevent migraine headache*

## TABLETS

**Adults.** *Initial:* 10 mg twice daily. *Maintenance:* 20 mg daily as a single dose or in divided doses. *Maximum:* 30 mg daily; discontinued after 8 wk, as prescribed, if maximum dose is ineffective.

Route	Onset	Peak	Duration
P.O.	30 min	1-2 hr	4-8 hr

## Mechanism of Action

Selectively blocks  $\alpha_1$  and  $\beta_2$  receptors in vascular smooth muscle and  $\beta_1$  receptors in the heart. This reduces peripheral vascular resistance and in turn blood pressure and relieves migraine headaches. Timolol's potent beta blockade prevents the reflex tachycardia that typically occurs with most alpha blockers, and decreases cardiac excitability, cardiac output, and myocardial oxygen demand, thus preventing MI.

## Contraindications

Acute bronchospasm; asthma; cardiogenic shock; children; COPD (severe); heart failure; hypersensitivity to timolol, other beta blockers, or their components; second- or third-degree AV block; severe sinus bradycardia

# Interactions

## DRUGS

*allergen immunotherapy, allergenic extracts for skin testing*: Increased risk of serious systemic adverse reactions or anaphylaxis

*amiodarone*: Additive depressant effect on cardiac conduction, negative inotropic effect

*anesthetics (hydrocarbon inhalation)*: Increased risk of hypotension and myocardial depression

*beta blockers*: Additive beta blockade effects

*calcium channel blockers, clonidine, diazoxide, guanabenz, reserpine, other hypotension-producing drugs*: Additive hypotensive effect and, possibly, other beta blockade effects

*cimetidine*: Possibly interference with timolol clearance

*estrogens*: Decreased antihypertensive effect of timolol

*fentanyl, fentanyl derivatives*: Possibly increased risk of initial bradycardia after induction doses of fentanyl or derivative (with long-term timolol use)

*glucagon*: Possibly blunted hyperglycemic response

*insulin, oral antidiabetic drugs*: Possibly masking of tachycardia in response to hypoglycemia, impaired glucose control

*lidocaine*: Decreased lidocaine clearance, increased risk of lidocaine toxicity

*MAO inhibitors*: Increased risk of significant hypertension

*neuromuscular blockers*: Possibly potentiated and prolonged action of these drugs

*NSAIDs*: Possibly decreased hypotensive effect

*phenothiazines*: Increased blood levels of both drugs

*phenytoin (parenteral)*: Additive cardiac depressant effect

*sympathomimetics, xanthines*: Possibly mutual inhibition of therapeutic effects

# Adverse Reactions

**CNS:** Asthenia, **CVA**, decreased concentration, depression, dizziness, fatigue, fever, hallucinations, headache, insomnia, nervousness, nightmares, paresthesia, syncope, vertigo

**CV:** Angina, **arrhythmias**, **bradycardia**, **cardiac arrest**, chest pain, edema, palpitations, Raynaud's phenomenon, vasodilation

**EENT:** Diplopia, dry eyes, eye irritation, ptosis, tinnitus, vision changes

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Abdominal pain, diarrhea, hepatomegaly, indigestion, nausea, vomiting

**GU:** Decreased libido, impotence

**MS:** Arthralgia, decreased tolerance to exercise, extremity pain, muscle weakness

**RESP:** **Bronchospasm**, cough, crackles, dyspnea

**SKIN:** Alopecia, diaphoresis, hyperpigmentation, pruritus, purpura, rash

**Other:** **Anaphylaxis**, weight loss

# Nursing Considerations

**WARNING** Be aware that timolol may mask evidence of acute hypoglycemia in diabetic patient. It also may mask certain signs of hyperthyroidism, such as tachycardia.

- Be aware that timolol may prolong hypoglycemia by interfering with glycogenolysis or may promote hyperglycemia by decreasing tissue sensitivity to insulin.
- Monitor blood pressure and cardiac output, as appropriate, for patient with a history of left ventricular dysfunction or systolic heart failure, because timolol's negative inotropic effect can depress cardiac output.

**WARNING** Be aware that timolol shouldn't be discontinued abruptly because this may produce MI, myocardial ischemia, severe hypertension, or ventricular arrhythmias, particularly in patient with known cardiovascular disease.

- Expect varied drug effectiveness in elderly patients; they may be less sensitive to drug's antihypertensive effect or more sensitive because of reduced drug clearance.
- Monitor for impaired circulation in elderly patients with age-related peripheral vascular disease or patients with Raynaud's phenomenon. Such patients may experience exacerbated symptoms from increased alpha stimulation. Elderly patients also are at increased risk for beta blocker-induced hypothermia.
- Know that if timolol worsens skin condition, such as psoriasis, prescriber should be notified.

## PATIENT TEACHING

- Instruct patient taking timolol to inform prescriber of chest pain, fainting, light-headedness, or shortness of breath, which may indicate the need for dosage change.
- Caution patient not to stop taking drug abruptly. Timolol dosage must be tapered gradually under prescriber's supervision.
- Instruct patient with diabetes to monitor blood glucose level often during therapy.
- Warn patient with psoriasis about possible flare-ups of skin condition.

**tinidazole**

**Tindamax**

# Class and Category

Pharmacologic class: **Nitroimidazole**

Therapeutic class: Antiprotozoal

Pregnancy category: C

# Indications and Dosages

- *To treat trichomoniasis caused by Trichomonas vaginalis*

## TABLETS

**Adults.** 2 g one time with food.

- *To treat giardiasis caused by Giardia duodenalis (G. lamblia)*

## TABLETS

**Adults.** 2 g one time with food.

**Children age 4 and over.** 50 mg/kg (up to 2 g) one time with food.

- *To treat intestinal amebiasis caused by Entamoeba histolytica*

## TABLETS

**Adults.** 2 g daily for 3 days with food.

**Children age 4 and over.** 50 mg/kg (up to 2 g) daily for 3 days with food.

- *To treat amebic liver abscess caused by E. histolytica*

## TABLETS

**Adults.** 2 g daily for 3 to 5 days with food.

**Children age 4 and over.** 50 mg/kg (up to 2 g) daily for 3 to 5 days with food.

➤ *To treat bacterial vaginosis in non-pregnant women*

## **TABLETS**

**Non-pregnant women.** 2 g once daily for 2 days with food. Alternatively, 1 g once daily for 5 days with food.

***DOSAGE ADJUSTMENT*** For patients receiving hemodialysis, an additional dose equivalent to one-half the dose prescribed should be given after the dialysis treatment on the days dialysis is performed.

## **Mechanism of Action**

Undergoes intracellular chemical reduction during anaerobic metabolism. After tinidazole is reduced, it damages DNA's helical structure and breaks its strands, which inhibits bacterial nucleic acid synthesis and causes cell death.

## **Contraindications**

Breastfeeding, hypersensitivity to tinidazole or its components, treatment of trichomoniasis during first trimester of pregnancy

## **Interactions**

### **DRUGS**

*cholestyramine:* Possibly decreased bioavailability of tinidazole

*cimetidine, ketoconazole:* Possibly delayed elimination and increased blood level of tinidazole

*cyclosporine, tacrolimus*: Possibly increased serum cyclosporine and tacrolimus levels

*disulfiram*: Possibly combined toxicity, resulting in confusion and psychosis

*fluorouracil*: Possibly decreased fluorouracil clearance

*lithium*: Possibly increased serum lithium levels

*oral anticoagulants*: Possibly increased anticoagulant effect

*oxytetracycline*: Possibly diminished effect of tinidazole

*phenobarbital, phenytoin, rifampin*: Possibly increased metabolism and decreased blood level of tinidazole

## ACTIVITIES

*alcohol use*: Possibly disulfiram-like effects

## Adverse Reactions

**CNS:** Ataxia, **coma**, confusion, depression, dizziness, drowsiness, fatigue, fever, headache, insomnia, malaise, peripheral neuropathy, **seizures**, vertigo, weakness

**CV:** Palpitations

**EENT:** Bitter or metallic taste, dry mouth, excessive salivation, furry tongue, oral candidiasis, pharyngitis, stomatitis, tongue discoloration

**GI:** Abdominal cramps, anorexia, constipation, diarrhea, epigastric discomfort, flatulence, hepatic abnormalities, indigestion, nausea, thirst, vomiting

**GU:** Darkened urine, dysuria, increased vaginal discharge, menorrhagia, UTI, vaginal candidiasis or odor, vulvo-vaginal discomfort

**HEME:** **Leukopenia, neutropenia, thrombocytopenia**

**MS:** Arthralgia, arthritis, myalgia, pelvic pain

**RESP:** **Bronchospasm**, dyspnea, upper respiratory tract infection

**SKIN:** Diaphoresis, **erythema multiforme**, flushing, pruritus, rash, **Stevens-Johnson syndrome**, urticaria  
**Other:** **Angioedema**

## Nursing Considerations

- Use tinidazole cautiously in patients with blood dyscrasias or CNS disease because tinidazole's adverse effects may worsen these disorders. Also use cautiously in patients with hepatic impairment because a chemically related drug has reduced elimination.
- Take seizure precautions. If a seizure or other abnormal neurologic symptoms occur, notify prescriber and expect to stop drug.
- Treat a patient diagnosed with trichomoniasis and her sexual partner with the same dose of tinidazole and at the same time, as ordered, because trichomoniasis is a sexually transmitted disease.
- Monitor patient's total WBC count and differential if retreatment with tinidazole is needed because adverse hematologic reactions may occur with repeated use.

## PATIENT TEACHING

- Tell patient to take tinidazole with food to minimize gastric discomfort.
- Instruct patient unable to swallow tablets to crush tinidazole and mix in artificial cherry syrup and then take with food.
- Advise patient to avoid alcohol while taking tinidazole and for 3 days afterward because alcohol can cause intense flushing.
- Tell patient to alert prescriber before taking tinidazole if she thinks or knows she is pregnant because tinidazole crosses the placental barrier during the first trimester and its effects on the fetus are unknown.
- Instruct breastfeeding patient not to breastfeed during therapy and for 3 days after taking last dose.

**tiotropium bromide**

# Spiriva HandiHaler, Spiriva Respimat

## Class and Category

*Pharmacologic class:* Anticholinergic

*Therapeutic class:* Bronchodilator

*Pregnancy category:* C

## Indications and Dosages

- *To provide long-term maintenance treatment of asthma*

### ORAL INHALATION (RESPIMAT)

**Adults and children age 6 and over.** 2.5 mcg (2 inhalations) once daily. *Maximum:* 2.5 mcg every 24 hr.

- *To provide long-term maintenance treatment of bronchospasm associated with COPD, including chronic bronchitis and emphysema; to reduce COPD exacerbations*

### ORAL INHALATION (HANDIHALER)

**Adults.** 18 mcg (2 inhalations) once daily. *Maximum:* 18 mcg every 24 hr.

### ORAL INHALATION (RESPIMAT)

**Adults.** 5 mcg (2 inhalations) once daily. *Maximum:* 5 mcg every 24 hr.

- *To provide maintenance treatment of asthma*

## ORAL INHALATION (RESPIMAT)

**Adults and children age 6 and over.** 2.5 mcg (2 inhalations) once daily. *Maximum:* 2.5 mcg every 24 hr.

## Mechanism of Action

Prevents acetylcholine from attaching to muscarinic receptors on membranes of smooth-muscle cells. By blocking acetylcholine's effects in the bronchi and bronchioles, tiotropium relaxes smooth muscles and causes bronchodilation.

## Contraindications

Hypersensitivity to atropine or its derivatives, including ipratropium, tiotropium, or their components

## Interactions

### DRUGS

*anticholinergics:* Possibly increased anticholinergic effects

## Adverse Reactions

**CNS:** **CVA**, depression, difficulty speaking, dizziness, insomnia, paresthesia

**CV:** Angina, **atrial fibrillation**, chest pain, hypercholesterolemia, hypertension, palpitations, peripheral edema, **supraventricular tachycardia**, tachycardia

**EENT:** Application site irritation (glossitis, mouth ulceration, pharyngolaryngeal pain), blurred vision, cataract, dry mouth, dysphonia, epistaxis, eye pain,

glaucoma, glossitis, hoarseness, increased intraocular pressure, laryngitis, oral candidiasis, pharyngitis, rhinitis, sinusitis, stomatitis, throat irritation, visual halos

**ENDO:** Hyperglycemia

**GI:** Abdominal pain, constipation, diarrhea, dysphagia, gastroesophageal reflux, indigestion, **intestinal obstruction**, ileus, vomiting

**GU:** Difficulty urinating, urine retention, UTI

**MS:** Arthritis, leg or skeletal pain, myalgia

**RESP:** Cough, **paradoxical bronchospasm**, upper respiratory tract infection

**SKIN:** Pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, candidiasis, dehydration, flu-like symptoms, **hypersensitivity reaction (immediate)**, infection

## Nursing Considerations

- Use tiotropium cautiously in patients with angle-closure glaucoma, benign prostatic hyperplasia, or bladder neck obstruction.

**WARNING** Monitor patient closely after giving first dose of tiotropium for immediate hypersensitivity reactions, including anaphylaxis, angioedema, bronchospasm, and skin reactions. If reaction occurs, notify prescriber and expect to stop tiotropium and provide supportive care. Know that patients with a hypersensitivity to atropine should not receive tiotropium, because tiotropium is a derivative of atropine. Also use tiotropium cautiously in patients who have severe hypersensitivity to milk proteins.

- Know that when tiotropium is used for maintenance therapy in patients with asthma, it may take up to 8 weeks to realize maximum benefits.

- Be aware that tiotropium should never be used to relieve acute bronchospasm.
- Monitor patient's renal function, as ordered, especially in patients with moderate to severe renal impairment, because tiotropium is excreted mainly by the kidneys. Monitor patient with renal dysfunction closely for anticholinergic effects.
- Monitor patient's pulmonary function, as ordered, to evaluate the effectiveness of tiotropium.

## **PATIENT TEACHING**

- Caution patient not to use tiotropium to treat acute bronchospasm and that drug should not be used more often than every 24 hours.
- Instruct patient on the proper use of the HandiHaler inhalation device, if prescribed. Tell patient to place the capsule into the center chamber of the inhalation device and then to press and release the button on the side of the inhalation device to pierce the capsule. Then have the patient exhale completely, close her lips around the mouthpiece, inhale slowly and deeply, and hold her breath for as long as is comfortable.
- Alert patient that the HandiHaler device should not be used to take any other drug and that the tiotropium capsule must be taken only using the device and never swallowed.
- Tell patient not to expose capsules used in the HandiHaler device to air until ready for use. To remove a capsule from the blister pack, tell patient to open the foil only as far as the stop line to avoid exposing the rest of the capsules in the blister pack to air. Instruct patient to discard capsules used in the HandiHaler device if they are inadvertently exposed to air and won't be used immediately.
- Advise patient to keep powder found in the capsule used with the HandiHaler device out of her eyes because it may irritate them or blur her vision.
- Tell patient prescribed the Respimat inhaler to insert the cartridge into the inhaler prior to first use and prime the device by actuating the inhaler (pointed toward the ground) until an aerosol cloud is visible and then repeat the process three more times. Remind patient that if the inhaler is not used for more than 3 days, the inhaler should be actuated once prior to use; if not used for more than 21 days, the inhaler should be activated three times prior to use.
- Inform patient that the Respimat inhaler should not be used to take any other drug.

- Instruct patient to rinse her mouth after each treatment to help minimize throat dryness and irritation.

**WARNING** Instruct patient to stop using drug and seek immediate emergency care if an acute allergic reaction occurs.

- Advise patient to tell prescriber about decreased response to tiotropium as well as difficulty urinating, eye pain, palpitations, and vision changes.

## tipranavir

### Aptivus

## Class and Category

*Pharmacologic class:* Protease inhibitor

*Therapeutic class:* Antiretroviral

*Pregnancy category:* C

## Indications and Dosages

- *As adjunct to treat human immunodeficiency virus type 1 (HIV-1) infection in patients who are treatment-experienced and infected with HIV-1 strains resistant to more than one protease inhibitor*

## CAPSULES, ORAL SOLUTION

**Adults.** 500 mg (2 capsules or 5 ml oral solution) coadministered with 200 mg of ritonavir twice daily, taken with or without meals.

**Children ages 2 to 18.** 14 mg/kg with 6 mg/kg of ritonavir (or 375 mg/m<sup>2</sup> coadministered with ritonavir 150 mg/m<sup>2</sup>) twice daily, taken with or without meals.

*Maximum:* 500 mg coadministered with ritonavir 200 mg twice daily.

**DOSAGE ADJUSTMENT** For children who develop intolerance or toxicity, dosage reduced to 12 mg/kg with 5 mg/kg ritonavir (or 290 mg/m<sup>2</sup> coadministered with 115 mg/m<sup>2</sup> ritonavir) twice daily, provided their virus is not resistant to multiple protease inhibitors.

## Mechanism of Action

Selectively inhibits the virus-specific processing of specific polyproteins in HIV-1 infected cells to prevent formation of mature virions.

## Contraindications

Coadministration with alfuzosin, amiodarone, bepridil, cisapride, dihydroergotamine, ergonovine, ergotamine, flecainide, lurasidone, lovastatin, methylergonovine, midazolam (oral), pimozide, propafenone, quinidine, rifampin, St. John's wort, sildenafil (for treatment of pulmonary arterial hypertension), simvastatin, triazolam; hypersensitivity to tipranavir or its components; moderate to severe hepatic impairment

## Interactions

### DRUGS

*abacavir, amprenavir, didanosine, etravirine, fosamprenavir, lopinavir, meperidine, methadone, omeprazole, raltegravir, saquinavir, valproic acid,*

*zidovudine*: Decreased concentration of these drugs with possible loss of therapeutic effect

*atazanavir*: Decreased concentration of atazanavir with possible decreased effectiveness and increased tipranavir concentration with possible increased effect and incidence of adverse reactions

*atorvastatin, bosentan, colchicine, desipramine, fluticasone, fluoxetine, itraconazole, ketoconazole, midazolam (parenteral), paroxetine, quetiapine, rifabutin, rilpivirine, rosuvastatin, salmeterol, sertraline, sildenafil, tadalafil, trazodone, vardenafil*: Increased concentration of these drugs, with possible increased effect and incidence of adverse reactions

*buprenorphine/naloxone, carbamazepine, phenobarbital, phenytoin*: Decreased concentration of tipranavir with possible decreased effectiveness

*calcium channel blockers, cyclosporine, pioglitazone, repaglinide, sirolimus, tacrolimus*: Possibly decreased concentration of these drugs with possible decreased effectiveness, or increased concentrations of these drugs with possible increased effect and incidence of adverse reactions

*clarithromycin*: Increased concentration of both drugs, with possible increased effects and incidences of adverse reactions

*disulfiram, metronidazole*: Possible increased disulfiram effect with tipranavir capsules because of alcohol content

*enfuvirtide, fluconazole*: Increased tipranavir concentration with possible increased effect and incidence of adverse reactions

*ethinyl estradiol-containing drugs*: Ethinyl estradiol concentrations decreased by as much as 50%, making oral contraceptive use ineffective; increased risk of estrogen deficiency in women taking drug as hormone replacement; increased risk of nonserious rash

*warfarin*: Possibly change in international normalized ratio (INR), with possible need for dosage change

## Adverse Reactions

**CNS:** Dizziness, fatigue, fever, headache, insomnia, **intracranial hemorrhage**, malaise, peripheral neuropathy, sleep disorder, somnolence

**CV:** Elevated cholesterol and triglyceride levels

**ENDO:** Diabetes mellitus, hyperglycemia

**GI:** Abdominal distention or pain, anorexia, diarrhea, dyspepsia, elevated liver and pancreatic enzymes, flatulence, gastroesophageal reflux disease, **hepatic failure**, **hepatic steatosis**, **hepatitis**, hyperbilirubinemia, nausea, **pancreatitis**, vomiting

**GU:** **Renal insufficiency**

**HEME:** Anemia, **leukopenia**, **neutropenia**, **thrombocytopenia**

**MS:** Myalgia, muscle cramp

**RESP:** Cough, dyspnea

**SKIN:** Exanthema, photosensitivity, pruritus, rash

**Other:** Dehydration, facial wasting, flu-like illness, **hypersensitivity reactions**, lipoatrophy, lipodystrophy (acquired), lipohypertrophy, **mitochondrial toxicity**, weight loss

## Nursing Considerations

- Know that use of tipranavir and ritonavir in treatment-naïve patients is not recommended.
- Be aware that genotypic or phenotypic testing and/or treatment history should guide tipranavir use.
- Use cautiously in patients with a co-infection with hepatitis B or C or who have elevated transaminase levels or mild hepatic impairment, because

these patients are at greater risk of experiencing tipranavir's adverse effect on the liver. Expect to have liver function tests done at initiation of therapy and then monitored frequently throughout course of treatment. Know that with asymptomatic elevations in ALT or AST greater than 10 times the upper normal limit or elevations between 5 and 10 times the upper normal limit, and patient's total bilirubin greater than 2.5 times the upper normal limit, expect drug to be discontinued. Also monitor patient for clinical signs and symptoms of hepatic dysfunction, such as acholic stools, anorexia, fatigue, jaundice, liver tenderness or enlargement, or nausea. Report findings to prescriber.

- Use cautiously in patients who are at risk for increased bleeding or who are receiving drugs known to increase risk of bleeding, because tipranavir may cause intracranial bleeding.
- Use cautiously in patients with a sulfa allergy, because tipranavir contains a sulfonamide moiety and cross-sensitivity between the two types of drugs is unknown.
- Expect patient's cholesterol and triglyceride levels to be checked before tipranavir therapy is begun and periodically throughout therapy, because drug may cause elevated lipid levels that may require treatment.
- Know that pediatric dosage of tipranavir is based on body weight or body surface area and should not exceed the recommended adult dose.
- Monitor patient for rash, which may become severe, though this is uncommon. If severe, notify prescriber, expect drug to be discontinued, and provide supportive care, as prescribed.
- Monitor patient's blood glucose level. Exacerbation of preexisting diabetes or new-onset diabetes mellitus has occurred in patients receiving protease inhibitor therapy such as tipranavir.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including tipranavir. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.
- Monitor patients with hemophilia, especially type A and B, because hemarthrosis and spontaneous skin hematomas have occurred with protease inhibitors.

## **PATIENT TEACHING**

- Tell patient to take tipranavir exactly as prescribed and not to alter dosage without prescriber knowledge. Also instruct patient to swallow capsule whole and not to chew or open capsules.
- Instruct patient to report a skin rash, sensitivity to the sun, or other symptoms such as blister formation, fever, generalized itching, joint pain or stiffness, peeling of skin, redness, or throat tightness and seek immediate medical attention. Also, advise patient to seek medical attention immediately if any unexplained or unusual bleeding or other reaction occurs.
- Tell patient prescribed oral solution form not to take supplemental vitamin E greater than a standard multivitamin, as oral solution of tipranavir contains higher amounts of vitamin E.
- Instruct patient to report any signs and symptoms of liver dysfunction, such as fatigue, loss of appetite, malaise, or yellowing of skin or white areas of her eyes.
- Tell patient to inform all prescribers of tipranavir therapy, because of multiple drug interactions associated with this drug. Stress importance of not taking any over-the-counter preparations, including herbals, without consulting prescriber.
- Inform women receiving estrogen-based hormonal contraceptives to use additional or alternative nonhormonal contraceptives during tipranavir therapy. Also, alert these women that they are at increased risk of developing a rash with tipranavir therapy.
- Inform mothers that breastfeeding should not be done during tipranavir therapy.

## tirofiban hydrochloride

**Aggrastat**

### **Class and Category**

*Pharmacologic class:* Glycoprotein IIb/IIIa receptor antagonist

*Therapeutic class:* Antiplatelet  
*Pregnancy category:* B

## Indications and Dosages

- *To reduce the rate of thrombotic cardiovascular events (combined endpoint of death, myocardial infarction, or refractory ischemia/repeat cardiac procedure) in patients with non-ST elevation acute coronary syndrome (NSTEMI-ACS)*

### I.V. INFUSION

**Adults. Initial:** 25 mcg/kg within 5 minutes and then 0.15 mcg/kg/min for up to 18 hr.

***DOSAGE ADJUSTMENT*** For patients with creatinine clearance of 60 ml/min or less, infusion rate reduced to 0.075 mcg/kg/min, for up to 18 hr.

Route	Onset	Peak	Duration
I.V.	Immediate	30 min	4-8 hr

## Mechanism of Action

Binds to glycoprotein IIb/IIIa receptor sites on the surface of activated platelets. Circulating fibrinogen can bind to these receptor sites and link platelets together, forming a clot that eventually blocks a coronary artery. By binding to receptor sites, tirofiban prevents the normal binding of fibrinogen and other factors and inhibits platelet aggregation.

## Incompatibilities

Don't infuse tirofiban in same I.V. line with any drug other than atropine sulfate, dobutamine, dopamine, epinephrine hydrochloride, furosemide, heparin, lidocaine, midazolam hydrochloride, morphine sulfate, nitroglycerin, potassium chloride, propranolol hydrochloride, or famotidine (Pepcid injection).

## Contraindications

Acute pericarditis; arteriovenous malformation; coagulopathy; stroke that occurred within previous 30 days or a history of hemorrhagic stroke; GI or GU bleeding; hemophilia; history of thrombocytopenia after tirofiban use; hypersensitivity to tirofiban or its components; intracranial aneurysm or mass, intracranial bleeding, retinal bleeding, aortic dissection, or any evidence of active abnormal bleeding within previous 30 days; major surgery or trauma within previous 6 weeks; severe uncontrolled hypertension (systolic blood pressure above 180 mm Hg, diastolic blood pressure above 110 mm Hg)

## Interactions

### DRUGS

*antineoplastics, antithymocyte globulin, NSAIDs, oral anticoagulants, platelet aggregation inhibitors, strontium-89 chloride, thrombolytics*: Increased risk of bleeding  
*levothyroxine, omeprazole*: Increased rate of tirofiban clearance

*porfimer*: Decreased effectiveness of porfimer photodynamic therapy

*salicylates*: Increased risk of bleeding, possibly hypoprothrombinemia

# Adverse Reactions

**CNS:** Chills, dizziness, fever, headache, **intracranial hemorrhage**

**CV:** Edema, **hemopericardium**, peripheral edema, sinus bradycardia

**GI:** **Hematemesis**, nausea, **retroperitoneal bleeding**, vomiting

**GU:** Hematuria, pelvic pain

**HEME:** **Severe bleeding, thrombocytopenia**

**RESP:** **Pulmonary hemorrhage**

**SKIN:** Diaphoresis, rash, urticaria

**Other:** **Anaphylaxis, hypersensitivity reactions**, infusion-site bleeding

# Nursing Considerations

**WARNING** Dilute 50-ml vial of tirofiban before use; don't dilute 500-ml container because it holds premixed solution ready for I.V. infusion. Don't use solution unless it's clear and the seal is intact.

**WARNING** Keep in mind that if patient is also receiving a heparin infusion, expect to monitor APTT before treatment, 6 hours after heparin infusion starts, and regularly thereafter. Expect to adjust heparin dosage to maintain APTT at about two times the control, as ordered. Notify prescriber immediately if patient develops an abnormally high APTT. Also, assess patient for signs and symptoms of abnormal bleeding and report them to prescriber immediately because potentially life-threatening bleeding may occur.

- Know that after cardiac catheterization or percutaneous transluminal coronary angioplasty, keep patient on bed rest with head of bed elevated. Ensure hemostasis of percutaneous site for at least 4 hours before

discharge. Minimize invasive procedures, including epidural procedures, to reduce the risk of bleeding.

- Monitor patient's hemoglobin level, hematocrit, and platelet count, as ordered. Expect to discontinue tirofiban if patient's platelet count is less than 90,000/mm<sup>3</sup>. Expect to give a platelet transfusion, as prescribed, if platelet count falls below 50,000/mm<sup>3</sup>.

## PATIENT TEACHING

- Advise patient to immediately report any bleeding, bruising, headache, pain, or swelling during I.V. infusion of tirofiban.

# tizanidine hydrochloride

## Zanaflex

## Class and Category

*Pharmacologic class:* Alpha<sub>2</sub> adrenergic agonist

*Therapeutic class:* Antispasmodic

*Pregnancy category:* C

## Indications and Dosages

- *To manage acute and intermittent increases of muscle tone with spasticity*

## CAPSULES, TABLETS

**Adults.** *Initial:* 2 to 4 mg every 6 to 8 hr, as needed, for maximum of 3 doses in 24 hr and then increased gradually by 2 to 4 mg/dose after 1 to 4 days, as needed and as

prescribed. *Maximum:* 16 mg as a single dose or 36 mg total daily.

**DOSAGE ADJUSTMENT** For patients with hepatic dysfunction or renal insufficiency, dosage reduced when drug is being titrated upward.

Route	Onset	Peak	Duration
P.O.	Unknown	1-2 hr	3-6 hr

## Mechanism of Action

Reduces spasticity by decreasing the release of excitatory amino acids. This  $\alpha_2$ -adrenergic agonist's action increases presynaptic inhibition of spinal motor neurons, with the greatest effects on polysynaptic pathways.

## Contraindications

Hypersensitivity to tizanidine or its components, use with ciprofloxacin or fluvoxamine

## Interactions

### DRUGS

*acetaminophen:* Delayed peak effects of acetaminophen

*$\alpha_2$ -adrenergic agonists:* Possibly significant hypotension

*antihypertensives:* Additive hypotensive effects

*CYP1A2 inhibitors (such as acyclovir, amiodarone, cimetidine, famotidine, mexiletine, propafenone, ticlopidine, verapamil, zileuton), fluoroquinolones*

*(including ciprofloxacin, fluvoxamine):* Possibly increased

plasma tizanidine level; increased risk of hypotension and sedation

*oral contraceptives:* Decreased tizanidine clearance

*rofecoxib:* Possibly increased adverse reactions

## ACTIVITIES

*alcohol use:* Increased adverse effects of tizanidine, additive CNS depression

## Adverse Reactions

**CNS:** Anxiety, delusions, drowsiness, dyskinesia, fatigue, fever, hallucinations, slurred speech

**CV:** Orthostatic hypotension

**EENT:** Dry mouth, pharyngitis, rhinitis

**GI:** Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, elevated liver enzymes, **hepatic failure**, **hepatomegaly**, jaundice, nausea, vomiting

**GU:** Urinary frequency, UTI

**MS:** Back pain, muscle weakness, myasthenia

**SKIN:** Diaphoresis, rash, ulceration

## Nursing Considerations

- Be aware that extreme caution is required if tizanidine is prescribed for a patient with hepatic impairment because the drug is extensively metabolized in the liver.
- Monitor hepatic and renal function for first 6 months and periodically thereafter.
- Expect prolonged drug use to inhibit saliva.
- Be aware that tizanidine should be stopped slowly to prevent rebound hypertension, tachycardia, and hypertonia as well as withdrawal.

## PATIENT TEACHING

- Caution patient not to stop taking tizanidine suddenly to prevent adverse effects.
- Advise patient to change positions slowly to minimize effects of orthostatic hypotension.
- Urge patient to avoid alcohol during drug therapy because of its additive CNS effects.
- Tell patient to notify dentist or prescriber if dry mouth lasts longer than 2 weeks.
- Instruct patient to inform all pharmacists and prescribers about any drug he starts or stops taking.

## tobramycin sulfate

**Bethkis, Kitabis Pak, Tobi, Tobi Podhaler, Tobramycin**

### Class and Category

*Pharmacologic class:* Aminoglycoside

*Therapeutic class:* Antibiotic

*Pregnancy category:* D

### Indications and Dosages

- *To treat bacteremia; bone and joint, gynecologic, intra-abdominal, lower respiratory tract, skin and soft-tissue, and urinary tract infections; endocarditis; meningitis; neonatal sepsis; pyelonephritis; and septicemia caused by susceptible strains of Acinetobacter species, Aeromonas species, Citrobacter species, Enterobacter species, Escherichia coli,*

*Haemophilus influenzae (beta lactamase-negative and -positive), Klebsiella species, Morganella morganii, Proteus mirabilis, Proteus vulgaris, Providencia rettgeri, Pseudomonas aeruginosa, Salmonella species, Serratia species, Shigella species, Staphylococcus aureus, and Staphylococcus epidermidis; to treat febrile neutropenia*

## **I.V. INFUSION, I.M. INJECTION (TOBRAMYCIN)**

**Adults with serious infection.** 1 mg/kg (over 20 to 60 minutes for I.V. infusion) every 8 hr.

**Adults with life-threatening infections.** 5 mg/kg (over 20 to 60 min for I.V. infusion) daily in three to four divided doses, reduced to 3 mg/kg (over 20 to 60 min for I.V. infusion) daily divided into 3 equal doses and given every 8 hr as soon as possible.

**Children and neonates over age 7 days.** 2 to 2.5 mg/kg (over 20 to 60 min for I.V. infusion) every 8 hr or 1.5 mg/kg every 6 hr.

**Premature or full term neonates age 7 days or less.** Up to 2 mg/kg (over 20 to 60 min for I.V. infusion) every 12 hr.

➤ *To treat pulmonary infection caused by P. aeruginosa in patients with cystic fibrosis*

## **I.M. INJECTION, I.V. INFUSION (TOBRAMYCIN)**

**Adults and children.** 2.5 mg/kg every 6 hr; dosage adjusted to achieve peak blood drug level of 8 to 12 mcg/ml and trough blood drug level below 2 mcg/ml. I.V. infusion given over 20 to 60 min.

## **INHALATION (BETHKIS, KITABIS PAK, TOBI)**

**Adults and children over age 6.** 1 ampule (300 mg) twice daily 12 hours apart in alternating periods of 28 days on and 28 days off.

## **INHALATION (TOBI PODHALER)**

**Adults and children 6 years and over.** Four 28 mg capsules inhaled using Podhaler every 12 hr in alternating periods of 28 days on and 28 days off.

**DOSAGE ADJUSTMENT** For patients with renal impairment, dosage possibly reduced or dosage interval increased.

## **Mechanism of Action**

Inhibits bacterial protein synthesis by binding irreversibly to one of two aminoglycoside-binding sites on the 30S ribosomal subunit, resulting in bacteriostatic effects. Bactericidal effects may stem from tobramycin's ability to accumulate within cells so that the intracellular drug level exceeds the extracellular level.

## **Incompatibilities**

Don't mix tobramycin in same solution with parenteral aminoglycosides or beta-lactam antibiotics because mutual inactivation may result. Don't dilute or mix inhalation solution in nebulizer with dornase alfa.

## **Contraindications**

Concurrent cidofovir, ethacrynic acid, furosemide, intravenous mannitol, or urea therapy; hypersensitivity to tobramycin, aminoglycosides, sodium bisulfite, or their components

# Interactions

## DRUGS

*acyclovir, aminoglycosides, amphotericin B, carboplatin, cisplatin, NSAIDs, vancomycin*: Additive nephrotoxicity  
*carbenicillin, ticarcillin*: Possibly inactivation of tobramycin  
*ethacrynic acid, furosemide*: Additive ototoxicity  
*ethacrynic acid, furosemide, mannitol, urea*: Increased risk of aminoglycoside toxicity  
*general anesthetics, neuromuscular blockers*: Possibly increased neuromuscular blockade  
*other drugs with nephrotoxic, neurotoxic, or ototoxic potential including systemic aminoglycosides*: Increased risk of nephrotoxicity, neurotoxicity, and ototoxicity

## Adverse Reactions

**CNS**: Confusion, dizziness, headache, inability to speak, lethargy, malaise **neurotoxicity**, vertigo

**EENT**: Hearing loss, laryngitis, oropharyngeal pain, ototoxicity, taste perversion, tinnitus, voice alteration

**GI**: Anorexia, ***Clostridium difficile-associated diarrhea***, diarrhea, elevated liver enzymes, nausea, vomiting

**GU**: Elevated BUN and serum creatinine levels, **nephrotoxicity**, oliguria, proteinuria, **renal failure**

**HEME**: Anemia, leukocytosis, **leukopenia**, **neutropenia**, **thrombocytopenia**

**MS**: Myalgia

**RESP**: **Bronchospasm**, discolored sputum, wheezing

**SKIN**: **Exfoliative dermatitis**, pruritus, rash, urticaria

**Other**: **Hypersensitivity reactions**, **hypocalcemia**, **hypokalemia**, **hypomagnesemia**, **hyponatremia**, injection-site pain

# Nursing Considerations

- Obtain fluid and tissue samples for culture and sensitivity testing before and during tobramycin therapy, as ordered. Review results, if available, before therapy starts.
- For I.V. administration, after reconstituting drug with 30 ml of sterile or bacteriostatic water for injection, dilute further with normal saline solution or D<sub>5</sub>W in volumes of 50 to 100 ml for adults. Less volume will be needed when diluting drug to be administered to infant or child. Check manufacturer guidelines for specific volume to use.
- Give each I.V. dose over 20 to 60 minutes.

**WARNING** Don't infuse tobramycin over less than 20 minutes to avoid neuromuscular blockade and excessive peak drug level.

- Don't expose ampules for inhalation solution to intense light. Refrigerate them at 2° to 8° C (36° to 46° F).
- Know that capsules for inhalation should be stored in the blister and each capsule removed immediately before use. Always administer tobramycin by Podhaler last, if other inhaled medications are being administered.
- Expect the serum concentration of tobramycin to be monitored only through venipuncture, as a finger-stick sample may lead to falsely increased measurements of serum levels of the drug, which cannot be completely avoided with handwashing before testing is done.
- Keep in mind that because drug can cause bilateral and irreversible hearing loss, assess for early signs of cochlear and vestibular ototoxicity, including ataxia, dizziness, high-frequency hearing loss, tinnitus, and vertigo. If present, expect an audiogram to be ordered. Drug may have to be discontinued.
- Monitor patient for bronchospasms and wheezing. Notify prescriber immediately if present and be prepared to treat, as prescribed.
- Monitor serum calcium, magnesium, potassium, and sodium levels to detect electrolyte imbalances.

**WARNING** Be alert for allergic reactions, including anaphylaxis.

- Stop tobramycin therapy 7 days before starting cidofovir therapy, as prescribed. Know that diuretics can increase risk of aminoglycoside toxicity by altering antibiotic concentrations in serum and tissue and therefore should not be administered with tobramycin.
- Watch for signs of nephrotoxicity, such as elevated BUN and serum creatinine levels. Be aware that patients with renal dysfunction or who are taking nephrotoxic drugs should have measurements of serum concentrations of tobramycin and renal function done as ordered by prescriber. If nephrotoxicity occurs, drug may have to be discontinued.
- Expect dehydration to increase the risk of nephrotoxicity.

**WARNING** Monitor patient with myasthenia gravis or Parkinsonism for increased muscle weakness because of tobramycin's potential curare-like effect.

- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis caused by *C. difficile*. If diarrhea occurs, notify prescriber, expect to withhold tobramycin, and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.

## **PATIENT TEACHING**

- Instruct patient on how to administer drug by inhalation. For inhaled tobramycin using ampules, instruct patient to inhale over 10 to 15 minutes, using a handheld nebulizer with a compressor. For inhaled tobramycin using capsules, instruct patient always to store capsules in the blister, not to remove capsules until immediately before use, and to use only with the Podhaler.
- Teach patient how to use nebulizer while sitting or standing upright and to breathe normally through its mouthpiece. Nose clips may help patient breathe through her mouth.
- Instruct patient to disinfect her nebulizer every other treatment day by boiling the nebulizer parts (except tubing) for a full 10 minutes and then drying the parts on a clean, lint-free cloth.
- Advise patient to notify prescriber if shortness of breath or wheezing occurs after administration of tobramycin inhalation solution.
- Urge patient to immediately report high-frequency hearing loss and vertigo.

- Instruct female patient to notify prescriber immediately about known or suspected pregnancy because drug poses danger to fetus.
- Advise mothers who are breastfeeding to monitor their infants for bloody or loose stools and for diaper rash or thrush, because tobramycin may cause intestinal flora alteration in the breastfed infant.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools may occur 2 or more months after antibiotic therapy and may be serious, requiring prompt treatment.
- Remind patient to alert all prescribers about tobramycin therapy, because drug interacts with many other drugs.

## tocilizumab

### Actemra

## Class and Category

*Pharmacologic class:* Monoclonal antibody (interleukin-6 receptor inhibitor)

*Therapeutic class:* Antiarthritic (disease-modifying antirheumatic drug [DMARD])

*Pregnancy category:* C

## Indications and Dosages

- *To treat moderate to severe active rheumatoid arthritis as monotherapy in patients who have had an inadequate response to one or more disease-modifying anti-rheumatic drugs (DMARDs) or as adjunct with methotrexate or other DMARDs*

## **I.V. INFUSION**

**Adults.** 4 mg/kg over 60 min every 4 wk, increased, as needed, to 8 mg/kg over 60 min every 4 wk. *Maximum: 800 mg per infusion.*

## **SUBCUTANEOUS INJECTION**

**Adults weighing 100 kg (220 lb) or more.** 162 mg every wk.

**Adults weighing less than 100 kg (220 lb).** 162 mg every other wk, followed by increased dosage frequency to every wk, as needed.

- *To treat active systemic juvenile idiopathic arthritis as monotherapy or as adjunct with methotrexate*

## **I.V. INFUSION**

**Children age 2 and over weighing 30 kg (66 lb) or more.** 8 mg/kg over 60 min every 2 wk.

**Children age 2 and over weighing less than 30 kg (66 lb).** 12 mg/kg over 60 min every 2 wk.

## **SUBCUTANEOUS INJECTION**

**Children age 2 and over weighing 30 kg (66 lb) or more.** 162 mg once every wk.

**Children age 2 and over weighing less than 30 kg (66 lb).** 162 mg every 2 wk.

- *To treat active polyarticular juvenile idiopathic arthritis*

## **I.V. INFUSION**

**Children age 2 and over weighing 30 kg (66 lb) or more.** 8 mg/kg over 60 min every 4 wk.

**Children age 2 and over weighing less than 30 kg (66 lb).** 10 mg/kg over 60 min every 4 wk.

## **SUBCUTANEOUS INJECTION**

**Children age 2 and over weighing 30 kg (66 lb) or more.** 162 mg once every 2 wk.

**Children age 2 and over weighing less than 30 kg (66 lb).** 162 mg once every 3 wk.

***DOSAGE ADJUSTMENT*** Dosage reduction or interruption of dosing for treatment of rheumatoid arthritis or interruption of dosing for polyarticular juvenile idiopathic arthritis and systemic juvenile idiopathic arthritis may be needed to manage dose-related laboratory abnormalities, including elevated liver enzymes, neutropenia, and thrombocytopenia.

➤ *To treat giant cell arteritis*

## **SUBCUTANEOUS INJECTION**

**Adults.** 162 mg once wk in combination with a tapering course of glucocorticoids. Alternatively, 162 mg once every other wk in combination with a tapering course of glucocorticoids.

➤ *To treat chimeric antigen receptor T-cell-induced severe or life-threatening cytokine release syndrome*

## **I.V. INFUSION**

**Adults and children age 2 and over weighing 30 kg (66 lb) or more.** 8 mg/kg infused over 1 hr with up to 3 more doses administered with at least 8 hours between doses, if needed. *Maximum:* 800 mg per infusion.

**Adults and children age 2 and over weighing less than 30 kg (66 lb).** 12 mg/kg infused over 1 hr with up to 3

more doses administered at least 8 hr between doses, if needed. *Maximum:* 800 mg per infusion.

## **Mechanism of Action**

Binds to interleukin 6 (IL-6) receptors to interrupt signaling through them. IL-6 is a proinflammatory cytokine produced by various cells, such as B- and T-cells, fibroblasts, lymphocytes, and monocytes. It is also produced by endothelial and synovial cells, leading to local production of IL-6 in joints affected by inflammatory processes such as polyarticular juvenile idiopathic arthritis, rheumatoid arthritis, and systemic juvenile idiopathic arthritis. Binding of IL-6 receptors prevents inflammation-related signals from being relayed, which reduces inflammatory response and relieves signs and symptoms of inflammatory-related arthritis.

## **Incompatibilities**

Don't mix tocilizumab with other drugs.

## **Contraindications**

Absolute neutrophil count below  $2,000/\text{mm}^3$ , hypersensitivity to tocilizumab or its components, liver enzymes (ALT or AST) above 1.5 times upper limit of normal, platelet count below  $100,000/\text{mm}^3$

## **Interactions**

### **DRUGS**

*anti-CD20 monoclonal antibodies, IL-1R antagonists, selective co-stimulation modulators, TNF antagonists:*

Increased risk of immunosuppression and infection  
*atorvastatin; cytochrome P-450 substrates with a narrow therapeutic index such as cyclosporine, theophylline, warfarin; CYP3A4 substrates such as lovastatin, oral contraceptives, simvastatin; omeprazole*: Possibly decreased plasma levels of these drugs with decreased effectiveness  
*live vaccines*: Increased risk of adverse vaccine effects

## Adverse Reactions

**CNS:** Demyelinating disorders, dizziness, headache

**CV:** Elevated lipid levels, hypertension

**EENT:** Nasopharyngitis, oral ulceration

**GI:** Diverticulitis, elevated liver enzymes, gastritis, gastroenteritis, hepatic impairment, **pancreatitis**, **perforation**, upper abdominal pain

**GU:** UTI

**HEME:** **Neutropenia**, **thrombocytopenia**

**MS:** Bacterial arthritis

**RESP:** Bronchitis, pneumonia, upper respiratory tract infection

**SKIN:** Cellulitis, generalized erythema, pruritus, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** **Anaphylaxis**, anti-tocilizumab antibodies, herpes zoster, **immunosuppression**, injection-site reactions (erythema, pain, pruritus, swelling), **malignancies**, infections including activation of latent infections, **sepsis**, tuberculosis with pulmonary or extrapulmonary disease

## Nursing Considerations

- Know that tocilizumab isn't recommended for patients with active liver disease or impairment because drug may adversely affect liver function.

- Make sure patient has a tuberculin skin test before therapy starts. If skin test is positive, tuberculosis treatment will need to be started before tocilizumab therapy can begin. Even patients who have tested negative for tuberculosis may develop tuberculosis during therapy. Monitor patient for low-grade fever, persistent cough, and wasting or weight loss; report such findings to prescriber.

**WARNING** Know that if patient has evidence of an active infection when drug is prescribed, therapy shouldn't start until infection has been treated. Monitor all patients for infections, including invasive fungal infections such as aspergillosis, candidiasis, or pneumocystis; or bacterial, mycobacterial, protozoal, or viral opportunistic infections during and after therapy, especially patients who are taking immunosuppressants. If a serious infection develops, expect prescriber to interrupt drug therapy until infection is controlled.

- Obtain a baseline of patient's absolute neutrophil count, liver enzymes, and platelet count before starting tocilizumab therapy, as ordered. Therapy shouldn't begin if patient's absolute neutrophil count is below  $2,000/\text{mm}^3$ , ALT or AST level is above 1.5 times the upper limit of normal, or platelet count is below  $100,000/\text{mm}^3$ . Monitor these values, as ordered, 4 to 8 weeks (2 to 4 weeks for systemic juvenile idiopathic arthritis) after drug is initiated and then every 3 months after that, and report abnormalities. Dosage adjustment may be required or drug may have to be discontinued if abnormalities occur. For example, drug should be discontinued if absolute neutrophil count drops below 500 per  $\text{mm}^3$ .
- Use tocilizumab cautiously in patients with recurrent infection or increased risk of infection, patients who live in regions where histoplasmosis and tuberculosis are endemic, and patients with a history of CNS demyelinating disorders because they may occur, although rarely, during tocilizumab therapy.
- Know that when to give tocilizumab intravenously, use either a 100-ml infusion bag or bottle (patients weighing 30 kg or more) or a 50-ml infusion bag or bottle (patients weighing less than 30 kg) containing 0.9% sodium chloride injection. Begin by withdrawing a volume equal to the volume of tocilizumab solution (patient's dose). Slowly add drug from each vial into infusion bag or bottle and gently invert bag to mix while avoiding foaming. Discard any unused drug left in vials. Once fully diluted,

solution may be stored in the refrigerator or at room temperature for up to 24 hours.

- Give tocilizumab with an infusion set, and never as I.V. push or bolus. Don't infuse concurrently with other drugs in same I.V. line.
- Know that when transitioning from intravenous therapy to subcutaneous therapy, the first subcutaneous dose should be given instead of next scheduled intravenous dose.

**WARNING** Stop tocilizumab immediately and notify prescriber if patient has an allergic reaction. Provide supportive care, as needed.

## PATIENT TEACHING

- Instruct patient or caregiver on how to administer drug subcutaneously, if prescribed. Remind patient or caregiver to rotate sites and never give injection into moles, scars, or areas where the skin is bruised, hard, not intact, red, or tender. Tell how to dispose of syringe properly and to keep syringes, including those discarded, out of reach of children and pets.
- Review the signs and symptoms of an allergic reaction (difficulty breathing, rash, swollen face), and tell patient to seek emergency care immediately if these occur.
- Stress importance of compliance with laboratory tests ordered to monitor for adverse reactions.
- Inform patient that infections, including activation of latent infections such as tuberculosis, may occur during tocilizumab therapy. Instruct him to report persistent, severe, or unusual signs and symptoms to prescriber.
- Instruct patient to contact a healthcare provider immediately about persistent, severe abdominal pain because it could reflect GI perforation.
- Advise patient to avoid people with infections and to have all prescribed laboratory tests performed.
- Inform patient that risk of developing a malignancy is higher in patients taking tocilizumab, but it is still rare. Emphasize importance of follow-up visits and reporting any sudden or unusual signs or symptoms.
- Caution against receiving live-virus vaccines while taking tocilizumab.
- Advise patient to inform all healthcare providers about tocilizumab use and to inform prescriber about any OTC medications being taken, including herbal remedies and mineral and vitamin supplements.

- Urge woman who becomes pregnant while receiving tocilizumab to contact prescriber and to join the pregnancy registry by calling 1-877-311-8972 so that exposure to tocilizumab can be monitored.
- Inform women to alert pediatrician of tocilizumab use during pregnancy before live or live-attenuated vaccines are given to the infant.

## tofacitinib citrate

**Xeljanz, Xeljanz XR**

### Class and Category

*Pharmacologic class:* Janus kinase inhibitor

*Therapeutic class:* Antirheumatic (disease-modifying antirheumatic drug [DMARD])

*Pregnancy category:* C

### Indications and Dosages

- *To treat moderate to severe active rheumatoid arthritis as monotherapy in patients who have had an inadequate response or intolerance to methotrexate; or as adjunct to methotrexate or other nonbiologic disease-modifying antirheumatic drugs (DMARDs); to treat psoriatic arthritis in patients who have had an inadequate response or intolerance to methotrexate or other DMARDs.*

### **TABLETS**

**Adults.** 5 mg twice daily.

## E.R. TABLETS

**Adults.** 11 mg once daily.

**DOSAGE ADJUSTMENT** For patients with moderate hepatic impairment or moderate or severe renal insufficiency, or patients taking concomitant CYP3A4 inhibitors such as ketoconazole, or concomitant use with one or more drugs that result in both potent inhibition of CYP2C19 such as fluconazole and moderate inhibition of CYP3A4, dosage reduced to 5 mg once daily.

➤ *To treat moderate to severe active ulcerative colitis*

## TABLETS

**Adults.** 10 mg twice daily for at least 8 wk followed by 5 or 10 mg twice daily, depending on therapeutic response.

**DOSAGE ADJUSTMENT** For patients taking a strong CYP3A4 inhibitor such as ketoconazole or a moderate CYP3A4 inhibitor with a strong CYP2C19 inhibitor such as fluconazole and for patients with moderate hepatic impairment or moderate to severe renal impairment, dosage reduced to 5 mg twice daily if patient was taking 10 mg twice daily, and dosage reduced to 5 mg once daily if patient was taking 5 mg twice daily. For patients with an absolute neutrophil count (ANC) between 500 and 1000 cells/mm<sup>3</sup>, dosage reduced to 5 mg twice daily if patient was taking 10 mg twice daily and dosage increased back to 10 mg twice daily when ANC is greater than 1000. For patients with a hemoglobin less than 8 g/dl or for patient who experiences a decrease of more than 2 g/dl, drug therapy interrupted until hemoglobin values have normalized. For patients who experience an ANC or lymphocyte count less than 500 cells/mm<sup>3</sup>, drug discontinued.

## Mechanism of Action

Modulates the signaling pathway by inhibiting the enzyme, Janus kinase (JAK). JAK is an intracellular enzyme which transmits signals arising from cytokine or growth factor-receptor interactions on the cellular membrane to influence cellular processes of hematopoiesis and immune cell function. Inhibiting the phosphorylation and activation of Signal Transducers and Activator of Transcription (STATs) needed to influence cellular processes lessens some of the signs and symptoms of rheumatoid arthritis.

## Contraindications

Hypersensitivity to tofacitinib or its components

## Interactions

### DRUGS

*azathioprine, cyclosporine, tacrolimus*: Potentiated immunosuppression

*CYP3A4 potent inducers such as rifampin*: Possibly loss or reduced effectiveness of tofacitinib

*live vaccines*: Increased risk of infection

*potent CYP3A4 inhibitors such as ketoconazole, moderate CYP3A4 inhibitors/potent CYP2C19 inhibitors such as fluconazole*: Increased tofacitinib exposure and adverse drug reactions

## Adverse Reactions

**CNS:** Fatigue, fever, headache, insomnia, paresthesia

**CV:** Elevated lipid levels, hypertension, peripheral edema

**EENT:** Esophageal candidiasis, nasopharyngitis, sinus congestion

**GI:** Abdominal pain, diarrhea, diverticulitis, dyspepsia, elevated liver enzymes, gastritis, hepatic steatosis, liver injury, nausea, vomiting

**GU:** Elevated serum creatinine levels, UTI

**HEME:** Anemia, **lymphopenia**, **neutropenia**

**MS:** Arthralgia, elevated creatine phosphokinase, joint swelling, musculoskeletal pain, tendonitis

**RESP:** Cough, dyspnea, **interstitial lung disease**, pneumonia, **pneumocystosis**, upper respiratory infection

**SKIN:** Cellulitis, erythema, **melanoma**, multidermatomal herpes zoster, **nonmelanoma skin cancers**, rash, pruritus

**Other:** Bacteria, mycobacterial, invasive fungal, viral or other opportunistic infections such as tuberculosis and other BK viral, cytomegalovirus, cryptococcus, or mycobacterial infections; dehydration; herpes zoster; **lymphoproliferative disorder**; **malignancies such as breast, colorectal, gastric, lung, lymphoma, malignant melanoma, prostate, and renal cell**

## Nursing Considerations

- Be aware tofacitinib therapy should not be given to a patient who has an active infection, including localized infections.
- Know that tofacitinib should not be given to patients with severe hepatic impairment; tofacitinib should not be initiated in patients with a lymphocyte count less than 500 cells/mm<sup>3</sup>, an absolute neutrophil count (ANC) less than 1,000 cells/mm<sup>3</sup>, or hemoglobin levels less than 9 g/dl.
- Check with patient to be sure past immunizations received are in line with current immunization guidelines before starting tofacitinib therapy. If the patient needs further immunizations, ensure that it is done before drug therapy begins.
- Screen patient for viral hepatitis, as ordered, prior to starting tofacitinib therapy.

- Check to be sure that the patient has been tested for latent or active tuberculosis before tofacitinib therapy begins. Antituberculosis therapy might be prescribed for patients with a past history of active or latent tuberculosis if completion of treatment cannot be verified. Also, patients who have a negative test for latent tuberculosis may also be prescribed antituberculosis therapy if they have risk factors for tuberculosis.
- Use extreme caution when administering drug to patients with a history of chronic or recurrent infections, exposure to tuberculosis, history of a serious infection or an opportunistic infection, have resided or traveled in areas of endemic mycoses or endemic tuberculosis, or have underlying conditions that may predispose them to infection.
- Use cautiously in patients with a known malignancy, other than successfully treated nonmelanoma skin cancer. The prescriber may choose to discontinue the drug in patients who develop a malignancy during tofacitinib therapy.
- Use cautiously in patients who may be at increased risk for gastrointestinal perforation, such as a patient with a history of diverticulitis. Monitor patient closely throughout tofacitinib therapy. Notify prescriber if patient experiences new onset abdominal symptoms suggestive of perforation.
- Use caution when administering nondeformable extended-release form of drug to patients with preexisting severe gastrointestinal narrowing. Rare reports of obstructive symptoms in patients with known strictures have occurred with other drugs utilizing a nondeformable extended-release formula.
- Obtain a CBC to determine patient's baseline, as ordered. Once the baseline is established, expect prescriber to order a lymphocyte level every 3 months; an ANC level after 4 to 8 weeks of therapy and then every 3 months; and a hemoglobin level after 4 to 8 weeks and then every 3 months. These test results will guide the prescriber in making modifications in the patient's treatment plan.
- Be aware that patient taking higher doses for the treatment of rheumatoid arthritis is at increased risk for developing a pulmonary embolism.
- Monitor the patient's liver enzymes routinely, as ordered, because drug has been associated with liver damage. Alert prescriber of any abnormalities and expect drug to be withheld during the investigation as to the cause of the elevated liver enzymes. If no other cause can be found, expect prescriber to discontinue the drug.
- Know that viral reactivation, including herpes virus reactivation (herpes zoster), has occurred with tofacitinib therapy.

- Expect prescriber to order a lipid profile on the patient 4 to 8 weeks after tofacitinib therapy has begun, because the drug has caused increases in lipid parameters generally within the first 6 weeks of therapy. Expect to manage hyperlipidemia, if present, according to clinical guidelines, as prescribed.
- Monitor patient for signs and symptoms of infection during and after tofacitinib therapy. Know that patients with diabetes mellitus are at increased risk for infection. Notify prescriber if an infection develops and expect to obtain a complete blood count, if ordered. Be aware that drug should be discontinued if the patient has an ANC count or lymphocyte count less than 500. If the patient has an ANC level between 500 and 1,000 or a hemoglobin level greater than a 2 g/dl decrease or less than 8 g/dl, expect drug therapy to be interrupted until the ANC and hemoglobin levels have returned to target range.

## **PATIENT TEACHING**

- Instruct patient to take tofacitinib exactly as prescribed.
- Alert patient that an inert tablet shell may be passed in her stool or via colostomy. If present, reassure her that the active medication has already been absorbed by the time patient sees the shell.
- Review infection control measures with patient as well as the signs and symptoms of an infection. If an infection occurs, tell patient to notify prescriber immediately.
- Make sure patient understands the serious adverse reactions associated with tofacitinib such as the development of malignancies and serious infections.
- Stress importance for women of childbearing age to use effective contraception during treatment and for at least 4 weeks after the last dose of tofacitinib. Tell female patient to notify prescriber if pregnancy is suspected or known because drug effect on the fetus is unknown. Encourage her to enroll in the pregnancy registry by calling 1-877-311-8972.
- Make women of childbearing age aware that breastfeeding should not be done while taking tofacitinib.
- Inform female patients that tofacitinib therapy may reduce fertility.
- Encourage patient to comply with laboratory blood tests needed to monitor patient's reaction to tofacitinib.

- Advise patient at increased risk for skin cancer to have a periodic skin examination.
- Warn patient to avoid live vaccines while taking tofacitinib.

## tolcapone

**Tasmar**

### Class and Category

*Pharmacologic class:* Catechol-O-Methyltransferase (COMPT) inhibitor

*Therapeutic class:* Antiparkinsonian

*Pregnancy category:* C

### Indications and Dosages

- *As adjunct (with levodopa and carbidopa) to treat idiopathic Parkinson's disease in patients who are experiencing symptom fluctuations and are not responding satisfactorily to or are not appropriate candidates for other adjunctive treatment*

#### **TABLETS**

**Adults.** *Initial:* 100 mg three times a day. *Maximum:* 200 mg three times a day.

### Mechanism of Action

Prolongs plasma half-life of levodopa by inhibiting catechol-*O*-methyltransferase (COMT), an enzyme responsible for metabolizing catecholamines—including dopa, dopamine, epinephrine, norepinephrine, and their hydroxylated metabolites. COMT inhibition decreases the metabolizing enzyme for levodopa, which yields a more sustained plasma levodopa level, making more available for diffusion into the CNS to be converted to dopamine.

## Contraindications

Confusion, hyperpyrexia, or rhabdomyolysis with previous use of tolcapone; hepatic dysfunction; hypersensitivity to tolcapone or its components

## Interactions

### DRUGS

*desipramine*: Possibly increased frequency of adverse effects

*levodopa*: Increased levodopa bioavailability, with increased risk of orthostatic hypotension and syncope

*MAO inhibitors*: Possibly inhibited catecholamine metabolism

## Adverse Reactions

**CNS:** Aggression, agitation, compulsive behaviors such as intense urges to perform certain activities excessively (binge eating, gambling, sex, or spending money), confusion, delirium, delusions, disorientation, dizziness, drowsiness, dyskinesia, fatigue, fever, hallucinations, headache, lethargy, loss of balance, paranoid ideation, psychotic-like behavior, somnolence

**CV:** Chest pain, orthostatic hypotension

**EENT:** Dry mouth

**GI:** Abdominal pain, **acute fulminant liver failure**, anorexia, cholestasis, constipation, diarrhea, elevated liver enzymes, jaundice, vomiting

**GU:** Bright yellow urine, hematuria

**MS:** Muscle cramps, **rhabdomyolysis**

**RESP:** Dyspnea, upper respiratory tract infection

**SKIN:** Diaphoresis

## Nursing Considerations

- Ensure that patient has had the risks of tolcapone therapy explained fully to him and has signed the acknowledgment form before starting therapy.
- Know that tolcapone should not be given to patient with a major psychotic disorder because of the increased risk of exacerbating psychosis.
- Use cautiously in patient with severe dyskinesia or dystonia because drug is known to cause rhabdomyolysis.
- Monitor liver enzymes, as ordered, during tolcapone therapy to detect hepatic impairment. Expect to discontinue drug if patient's liver enzymes exceed twice the upper limit of normal or if patient has any signs or symptoms of liver dysfunction, such as persistent anorexia, dark urine, fatigue, jaundice, lethargy, nausea, pruritus, or right upper quadrant tenderness.
- Assess patient for behavioral changes, hallucinations, or new or worsening mental status during tolcapone therapy or after starting or increasing the dose, especially in patients over age 75. If present, notify prescriber as dosage may need to be reduced or drug discontinued.
- Anticipate that drug may precipitate or exaggerate preexisting dyskinesia.
- Expect tolcapone to be discontinued if no improvement occurs after 3 weeks of drug therapy.
- Assess patient for skin changes regularly because risk of melanoma is higher in patients with Parkinson's disease. It isn't clear whether risk results from disease or drugs used to treat it.

## PATIENT TEACHING

- Inform patient that urine may turn bright yellow during tolcapone therapy.
- Advise patient to avoid hazardous activities until drug's CNS effects are known. Inform patient that tolcapone therapy may cause him to fall asleep suddenly during activities of daily living without warning and can occur for the first time even a year after therapy has begun. If this happens, tell patient to notify prescriber and continue to avoid hazardous activities until prescriber has deemed such activities safe. Also warn patient and family that behavioral changes, hallucinations, or new or worsening mental status have occurred with use of tolcapone, especially in patients over the age of 75.
- Urge patient to notify prescriber immediately about darkened urine, decreased appetite, fatigue, jaundice, lethargy, and right-sided abdominal pain.
- Caution patient not to stop taking drug abruptly. Explain that prescriber will supervise tapering of drug dosage.
- Urge patient to have regular follow-up appointments and laboratory tests.
- Urge patient to have regular skin examinations by a dermatologist or other qualified health professional.
- Advise patient to notify prescriber about intense urges that result in performing certain behaviors excessively (such as binge eating, uncontrolled gambling, sex, or spending money) because dosage may need to be reduced or drug discontinued.

## tolterodine tartrate

**Detrol, Detrol LA**

### **Class and Category**

*Pharmacologic class:* Cholinergic receptor blocker

*Therapeutic class:* Antispasmodic

*Pregnancy category:* C

# Indications and Dosages

➤ *To treat overactive bladder*

## **TABLETS**

**Adults.** 2 mg twice daily. Reduced to 1 mg twice daily based on patient response and tolerance.

***DOSAGE ADJUSTMENT*** Dosage reduced to 1 mg twice daily for patients with significant hepatic or renal dysfunction and for patients who are also receiving cytochrome P-450 3A4 inhibitors, such as antifungals (itraconazole, ketoconazole, and miconazole), clarithromycin, cyclosporine, erythromycin, and vinblastine.

## **E.R. CAPSULES**

**Adults.** 4 mg daily. Reduced to 2 mg daily based on individual response and tolerance.

***DOSAGE ADJUSTMENT*** For patients with mild to moderate hepatic dysfunction, severe renal dysfunction, and for patients receiving cytochrome P-450 3A4 inhibitors, such as clarithromycin, itraconazole, ketoconazole, or ritonavir, dosage reduced to 2 mg once daily.

## **Mechanism of Action**

Exerts antimuscarinic (atropine-like) and potent direct antispasmodic (papaverine-like) actions on smooth muscle in the bladder, which decreases detrusor muscle contractions. This helps reduce urinary frequency and urgency as well as urge-related incontinence.

## **Contraindications**

Gastric retention; hypersensitivity to tolterodine tartrate, its components, or to fesoterodine fumarate extended-release tablets; uncontrolled angle-closure glaucoma; urine retention

## Interactions

### DRUGS

*class IA antiarrhythmics (such as procainamide, quinidine) or class III antiarrhythmics (such as amiodarone, sotalol):*

Possibly increased risk of prolonged QT interval

*fluoxetine:* Possibly decreased tolterodine metabolism

*potent CYP3A4 inhibitors such as clarithromycin, cyclosporine, erythromycin, itraconazole, ketoconazole, miconazole ritonavir, vinblastine:* Possibly increased blood tolterodine level

## Adverse Reactions

**CNS:** Confusion, disorientation, dizziness, drowsiness, fatigue, hallucinations, headache, memory impairment, somnolence, worsening of dementia

**CV:** Chest pain, edema, hypertension, palpitations, **QT prolongation**, tachycardia

**EENT:** Abnormal vision, blurred vision, dry eyes, dry mouth

**GI:** Abdominal pain, constipation, diarrhea, flatulence, indigestion, nausea

**GU:** Dysuria, urine retention, UTI

**Other:** **Anaphylaxis**, **angioedema**, flu-like symptoms

## Nursing Considerations

- Use cautiously in patients with decreased GI motility, myasthenia gravis, or narrow-angle glaucoma because tolterodine could make these

conditions worse.

***WARNING*** Monitor patients with a history of bladder outflow obstruction for bladder distention or decreased urine output because tolterodine poses a risk of urine retention.

- Monitor patients for abdominal bloating or distention or patients with a history of GI obstructive disorders, such as pyloric stenosis, because of increased risk of gastric retention.
- Be aware that drug's antimuscarinic effects may produce blurred vision, dizziness, and drowsiness. If these occur, institute fall precautions according to facility policy.

## **PATIENT TEACHING**

- Instruct patient taking tolterodine to report immediately to prescriber any difficulty urinating or infrequent urination, as well as difficulty breathing or swelling that involves the face, lips, throat or tongue, and to seek emergency medical care.
- Advise patient not to drive or perform activities that require high alertness until drug's CNS and vision effects are known. Instruct her to notify prescriber if blurred vision, dizziness, or drowsiness persists.
- Encourage patient to use sugarless candy, gum, or ice to relieve dry mouth. Advise her to notify prescriber or dentist if dry mouth persists or worsens over 2 weeks.

**tolvaptan**

**Samsca**

## **Class and Category**

*Pharmacologic class:* Vasopressin receptor antagonist

*Therapeutic class: Vasopressin antagonist*

*Pregnancy category: C*

## Indications and Dosages

- *To treat significant hypervolemic and euvolemic hyponatremia (serum sodium level less than 125 mEq/L or symptomatic but less-marked hyponatremia that has resisted correction with fluid restriction), including patients with heart failure or syndrome of inappropriate antidiuretic hormone (SIADH)*

### **TABLETS**

**Adults.** *Initial:* 15 mg once daily, increased after at least 24 hours to 30 mg once daily. *Maximum:* 60 mg once daily for 30 days or less.

## Mechanism of Action

Raises serum sodium levels by decreasing urine osmolality and increasing urine output. Tolvaptan does this by preventing attachment of vasopressin to vasopressin V2 receptors on cell membranes in the nephron's collecting duct. Without vasopressin activity, urinary water excretion increases.

## Contraindications

Acute need to raise serum sodium urgently; anuria; concomitant use of strong CYP3A inhibitors such as clarithromycin, ketoconazole, indinavir, itraconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin; hypovolemic hyponatremia; hypersensitivity to tolvaptan or

its components; inability of patient to sense or respond appropriately to thirst

## Interactions

### DRUGS

*ACE inhibitors, angiotensin receptor blockers, potassium sparing diuretics, potassium supplements:* Increased risk of hyperkalemia

*CYP3A inducers such as barbiturates, carbamazepine, phenytoin, rifabutin, rifampin, rifapentine, St. John's wort:* Decreased serum tolvaptan level and decreased effectiveness

*CYP3A inhibitors such as aprepitant, clarithromycin, diltiazem, erythromycin, fluconazole, ketoconazole, indinavir, itraconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, verapamil; P-gp inhibitors such as cyclosporine:* Increased serum tolvaptan level and risk of adverse reactions

*desmopressin:* Possibly altered desmopressin activity

*digoxin:* Increased digoxin level

### FOODS

*grapefruit juice:* Increased serum tolvaptan level

## Adverse Reactions

**CNS:** Asthenia, **CVA**, fever, **osmotic demyelination syndrome**, thirst

**CV:** **Deep vein thrombosis**, **intracardiac thrombus**, **ventricular fibrillation**

**EENT:** Dry mouth

**ENDO:** **Diabetic ketoacidosis**, hyperglycemia

**GI:** Anorexia, constipation, **GI bleeding**, hepatic dysfunction, **hepatic injury**, **ischemic colitis**, nausea  
**GU:** Nocturia, polyuria, **urethral or vaginal hemorrhage**  
**HEME:** **Disseminated intravascular coagulation (DIC)**, **prolonged prothrombin time**  
**MS:** **Rhabdomyolysis**  
**RESP:** **Pulmonary embolism**, **respiratory failure**  
**SKIN:** Rash  
**Other:** **Anaphylaxis**, dehydration, **hyperkalemia**, **hypernatremia**, **hyponatremia**, hypovolemia

## Nursing Considerations

- Be aware that tolvaptan should not be given to patients with a creatine clearance of less than 10 ml/min because no benefit can be expected in patients who are anuric. Also know that tolvaptan should not be used to treat autosomal dominant polycystic kidney disease, because of the risk of hepatotoxicity.
- Use cautiously in patients with cirrhosis because of increased risk of GI bleeding.

**WARNING** Give tolvaptan, initially or if reintroduced, in a hospital setting because too-rapid correction of hyponatremia (more than 12 mEq/L in 24 hour) causes osmotic demyelination (affective changes, coma, dysarthria, dysphagia, lethargy, mutism, spastic quadriparesis, seizures, death). If present, notify prescriber immediately and expect to stop tolvaptan and give hypotonic fluids.

- Monitor fluid and electrolyte balance regularly, especially when starting tolvaptan and adjusting dosage, as ordered. If patient develops hypernatremia, notify prescriber and expect to decrease dose or withhold drug and modify the patient's free-water infusion or intake, as ordered.
- Don't restrict fluids during first 24 hours of therapy because doing so may increase the risk of overly rapid correction of dehydration, hypovolemia,

and serum sodium.

- Use of hypertonic saline isn't recommended during tolvaptan therapy because effects are unknown.
- Monitor patient for signs and symptoms of hepatic dysfunction such as anorexia, dark urine, fatigue, jaundice, and right upper abdominal pain; if present, notify prescriber, and obtain liver enzymes immediately, as ordered. Be aware that to minimize risk of liver injury that could become life-threatening, drug should not be given longer than 30 days. If hepatic dysfunction is confirmed, expect drug to be discontinued. Know that if the cause of hepatic dysfunction is found to be due to something other than tolvaptan therapy, expect drug to be resumed.

## PATIENT TEACHING

- Instruct patient to consume fluids according to thirst during first 24 hours of therapy and not to try to limit fluid intake.
- Tell patient that he'll need to resume fluid restriction and will need continued monitoring of sodium level and fluid status when drug is discontinued.
- Tell patient to notify prescriber if he experiences dark urine or yellowing of eyes and skin, fatigue, loss of appetite, or right upper abdominal pain.

## topiramate

**Qudexy XR, Topamax, Trokendi XR**

## Class and Category

*Pharmacologic class:* Sulfamate-substituted monosaccharide

*Therapeutic class:* Anticonvulsant

*Pregnancy category:* D

# Indications and Dosages

- *To treat partial-onset or primary generalized tonic-clonic seizures*

## **CAPSULES, TABLETS (TOPAMAX)**

**Adults and children age 10 and over.** *Initial:* 25 mg twice daily in morning and evening for wk 1; 50 mg twice daily in morning and evening for wk 2; 75 mg twice daily in morning and evening for wk 3; 100 mg twice daily in morning and evening for wk 4; 150 mg twice daily in morning and evening for wk 5; and 200 mg twice daily in morning and evening for wk 6. *Maintenance:* 200 mg twice daily in morning and evening.

**Children age 2 to 10 years of age.** *Initial:* 25 mg once daily in evening for wk 1. Increased to 25 mg twice daily in morning and evening for wk 2. Increased thereafter by 25 to 50 mg/day each subsequent wk, as tolerated, over the next 5 wk. *Maintenance:* For children weighing up to 11 kg (up to 24.2 lb), 75 to 125 mg twice daily; for children weighing 12 to 22 kg (26.4 to 48.4 lb), 100 to 150 mg twice daily; for children weighing 23 to 31 kg (50.6 to 68.2 lb), 100 to 175 mg twice daily; for children weighing 32 to 38 kg (70.4 to 83.6 lb), 125 to 175 mg twice daily; and for children weighing more than 38 kg (more than 83.6 lb), 125 to 200 mg twice daily. *Maximum:* Highest maintenance dosage for weight.

## **EXTENDED-RELEASE CAPSULES (QUDEXY XR, TROKENDI XR)**

**Adults and children age 10 and over.** *Initial:* 50 mg once daily for wk 1; 100 mg once daily for wk 2; 150 mg once daily for wk 3; 200 mg once daily for wk 4; 300 mg once

daily for wk 5; and 400 mg once daily for wk 6 and beyond.  
*Maintenance:* 400 mg once daily.

## **EXTENDED-RELEASE CAPSULES (QUDEXY XR, TROKENDI XR)**

**Children age 2 to less than 10 (Qudexy XR) and children age 6 to less than 10 (Trokendi XR).** *Initial:* 25 mg once daily at night for wk 1; 50 mg once daily at night for wk 2; then increased weekly in increments of 25 to 50 mg until minimum maintenance dose reached, usually within 5 to 7 wk. Additional increases in increments of 25 to 50 mg made weekly to maximum maintenance dose, as needed. *Maintenance:* For children weighing up to 11 kg (24.2 lb), 150 to 250 mg once daily at night; for children weighing 12 to 22 kg (26.4 to 48.4 lb), 200 to 300 mg once daily at night; for children weighing 23 to 31 kg (50.6 to 68.2 lb), 200 to 350 mg once daily at night; for children weighing 32 to 38 kg (70.4 to 83.6 lb), 250 to 350 mg once daily at night; and for children weighing more than 38 kg (83.6 lb), 250 to 400 mg once daily at night. *Maximum:* Highest maximum maintenance dose for weight.

- *As adjunct to treat partial seizures and primary generalized tonic-clonic seizures*

## **CAPSULES, TABLETS (TOPAMAX)**

**Adults and adolescents age 17 and over.** *Initial:* 25 to 50 mg daily in divided doses twice daily for 1 wk. Increased by 25 to 50 mg daily every wk thereafter until maintenance dose is reached. *Maintenance:* 200 to 400 mg daily in divided doses twice daily for partial onset seizures and 400 mg daily in divided doses twice daily for primary generalized tonic-clonic seizures.

**Children ages 2 to 16.** *Initial:* 1 mg/kg/day to 3 mg/kg daily at night for 1 wk. Increased every 1 to 2 wk by 1 to 3

mg/kg daily in divided doses twice daily until maintenance dose is reached. *Maintenance:* 5 to 9 mg/kg daily in divided doses twice daily.

## **EXTENDED-RELEASE CAPSULES (QUDEXY XR)**

**Adults and adolescents age 17 and over.** *Initial:* 25 to 50 mg once daily, increased weekly in increments of 25 to 50 mg once daily, as needed. *Maximum:* 400 mg once daily.

**Children age 2 to 16 years of age.** *Initial:* 1 to 3 mg/kg/day once daily at night for 1 wk, increased every 1 to 2 wk in increments of 1 to 3 mg/kg/day, as needed. *Maximum:* 9 mg/kg/day.

## **EXTENDED-RELEASE CAPSULES (TROKENDI XR)**

**Children age 6 to 16 years of age.** *Initial:* 1 to 3 mg/kg/day once daily at night for 1 wk, increased every 1 to 2 wk in increments of 1 to 3 mg/kg/day, as needed. *Maximum:* 9 mg/kg/day.

► *As adjunct to treat seizures associated with Lennox-Gastaut syndrome*

## **CAPSULES, TABLETS (TOPAMAX)**

**Adults and adolescents age 17 and over.** 25 to 50 mg daily in divided doses twice daily for 1 wk. Increased by 25 to 50 mg daily every wk thereafter until maintenance dose is reached. *Maintenance:* 200 to 400 mg daily in divided doses twice daily.

**Children ages 2 to 16.** *Initial:* 1 to 3 mg/kg/day at night for 1 wk. Increased every 1 to 2 wk by 1 to 3 mg/kg daily in divided doses twice daily until maintenance dose is reached. *Maintenance:* 5 to 9 mg/kg daily in divided doses twice daily.

## **EXTENDED-RELEASE CAPSULES (TROKENDI XR)**

**Adults and adolescents age 17 and over.** *Initial:* 25 to 50 mg once daily, increased weekly in increments of 25 to 50 mg once daily, as needed. *Maximum:* 400 mg once daily.

**Children age 6 to 16 years of age.** *Initial:* 1 to 3 mg/kg/day once daily at night for 1 wk, increased every 1 to 2 wk in increments of 1 to 3 mg/kg/day, as needed. *Maximum:* 9 mg/kg/day.

## **EXTENDED-RELEASE CAPSULES (QUDEXY XR)**

**Adults and adolescents age 17 and over.** *Initial:* 25 to 50 mg once daily, increased weekly in increments of 25 to 50 mg once daily, as needed. *Maximum:* 400 mg once daily.

**Children age 2 to 16 years of age.** *Initial:* 1 to 3 mg/kg/day once daily at night for 1 wk., increased every 1 to 2 wk in increments of 1 to 3 mg/kg/day, as needed. *Maximum:* 9 mg/kg/day.

➤ *To prevent migraine headache*

## **CAPSULES, TABLETS (QUDEXY XR, TOPAMAX)**

**Adults and children age 12 and over.** *Initial:* 25 mg daily in evening for wk 1; then 25 mg twice daily morning and evening for wk 2; then 25 mg in morning and 50 mg in evening for wk 3, then 50 mg twice daily in morning and evening. *Maintenance:* 50 mg twice daily.

***DOSAGE ADJUSTMENT*** For patients with moderate to severe renal impairment, dosage possibly reduced by 50%. For patients undergoing hemodialysis, a supplemental dose may be required during a prolonged period of dialysis. For patients taking carbamazepine and/or phenytoin, a dosage adjustment may be required.

## **Mechanism of Action**

May block the spread of seizures by reducing the length and frequency of excitatory transmission. Topiramate increases the availability of the inhibitory neurotransmitter gamma-aminobutyric acid by blocking voltage-sensitive sodium channels. This action promotes the movement of chloride ions into neurons.

## Contraindications

Hypersensitivity to topiramate or its components, metabolic acidosis with concurrent metformin use (Trokendi XR), recent alcohol use defined as within 6 hours prior to and 6 hours after taking topiramate (Trokendi XR)

## Interactions

### DRUGS

*amitriptyline*: Possibly high increase in amitriptyline blood concentration increasing risk of adverse reactions

*antihistamines, barbiturates, benzodiazepines, CNS depressants, opioid analgesics, skeletal muscle relaxants, tricyclic antidepressants*: Additive CNS depression

*carbamazepine, phenytoin*: Decreased blood topiramate level

*digoxin*: Possibly decreased blood digoxin level

*ethinyl estradiol*: Increased risk of breakthrough bleeding

*hydrochlorothiazide*: Possibly increased blood topiramate levels

*lithium*: Increased risk of lithium toxicity

*oral contraceptives*: Increased risk of breakthrough bleeding, decreased contraceptive efficacy

*other carbonic anhydrase inhibitors such as acetazolamide, dichlorphenamide, zonisamide*: Increased risk of kidney stone formation; increased severity of metabolic acidosis

*phenobarbital*: Altered blood phenobarbital level  
*pioglitazone*: Possibly decreased exposure of pioglitazone with decreased effectiveness  
*probenecid*: Possibly blocked renal tubular reabsorption of topiramate and decreased blood topiramate level  
*valproic acid*: Decreased blood levels of both drugs, increased risk of hyperammonemia or hypothermia  
*warfarin*: Decreased International Normalized Ratio (INR) or prothrombin time

## ACTIVITIES

*alcohol use*: Additive CNS depression

## Adverse Reactions

**CNS:** Abnormal coordination, aggression, agitation, anxiety, aphasia, apathy, asthenia, ataxia, confusion, decreased concentration, depersonalization, depression, dizziness, dysphasia, emotional lability, **encephalopathy**, fatigue, fever, gait abnormality, hallucinations, headache, hyperkinesia, hyperthermia, hypoesthesia, hyporeflexia, insomnia, irritability, language problems, memory alterations or loss, mood changes, nervousness, neurosis, paresthesia, personality disorder, psychomotor slowing, psychosis, rigors, **seizures**, slurred or other abnormalities of speech, somnolence, stupor, **suicidal ideation**, syncope, thirst, tremor, vertigo

**CV:** **Bradycardia**, **cardiac arrest**, chest pain, edema, hypertension, **hypotension**, palpitations, vasodilation

**EENT:** Blurred vision, conjunctivitis, diplopia, dry mouth, edema of the pharynx, gingivitis, glossitis, gum hyperplasia, hearing loss, increased saliva, laryngitis, maculopathy, myopia, nystagmus, otitis media, periorbital pain, pharyngitis, rhinitis, secondary angle-closure

glaucoma with acute myopia, sinusitis, taste loss or perversion, tinnitus, tongue edema, vision changes including visual field defects

**ENDO:** Breast pain, hot flashes, hyperglycemia, **hypoglycemia**, hypothyroidism

**GI:** Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, fecal incontinence, flatulence, gastroenteritis, gastroesophageal reflux, **hepatic failure**, **hepatitis**, increased appetite, indigestion, nausea, **pancreatitis**, vomiting

**GU:** Cystitis, decreased libido, dysmenorrhea, dysuria, frequent urination, hematuria, impotence, leukorrhea, menstrual irregularities, nocturia, premature ejaculation, prostatic disorder, renal calculi, renal tubular acidosis, urinary frequency or incontinence, UTI, vaginitis

**HEME:** Anemia, **bleeding events**, **increased prothrombin time**, **leukopenia**, purpura, **thrombocytopenia**

**MS:** Arthralgia, back pain, dysarthria, involuntary muscle contractions, leg cramps or pain, muscle weakness, myalgia, skeletal pain

**RESP:** Bronchitis, cough, dyspnea, pneumonia, **pulmonary embolism**, upper respiratory tract infection

**SKIN:** Abnormal hair growth, acne, alopecia, bullous skin reactions, decreased or increased sweating, dermatitis, **erythema multiforme**, eczema, flushing, pallor, pemphigus, pruritus, rash, seborrhea, skin discoloration, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** Body odor, **decreased serum bicarbonate levels**, dehydration, elevated serum alkaline phosphatase, flu-like symptoms, **hyperammonemia**, **hypersensitivity reactions**, **hyponatremia**, **hypophosphatemia**, increased susceptibility to infection, **metabolic acidosis**, moniliasis, weight gain or loss

# Nursing Considerations

- Obtain baseline serum bicarbonate level before topiramate therapy and monitor periodically throughout therapy, as ordered.
- Use topiramate cautiously in patients with impaired hepatic function, or inborn errors of metabolism, or those who are taking valproic acid; these patients may be at higher risk for hyperammonemia, with or without encephalopathy, while taking topiramate. In addition, hypothermia may occur in patients taking valproic acid concomitantly. If present, notify prescriber and expect topiramate or valproic acid therapy to be discontinued.
- Give capsule with water and have patient swallow it whole. If needed, open capsules and empty contents onto a spoonful of soft food. Discard unused portion.
- Never store food sprinkled with drug for use at a later time.

**WARNING** Anticipate an increase in seizure activity if topiramate therapy for seizures stops abruptly. Take seizure precautions, as appropriate. Expect drug to be withdrawn gradually if time permits.

- Keep in mind that if patient reports ocular pain or decreased visual acuity, notify prescriber immediately; topiramate may cause increased intraocular pressure and secondary angle-closure glaucoma as well as visual field defects. Expect to stop drug immediately.
- Monitor patient for cognitive-related dysfunction, especially patients who are started on a higher initial dose or have a rapid titration rate.
- Assess for signs of recurrence of renal calculi if patient has a history of this condition.
- Monitor patient for bleeding events, especially patients who have conditions that increase risk of bleeding, who take drugs that cause thrombocytopenia such as other antiepileptic drugs, or who take drugs that affect platelet function or coagulation such as anticoagulants aspirin, nonsteroidal anti-inflammatory drugs, or selective serotonin reuptake inhibitors.

## PATIENT TEACHING

- Instruct patient to swallow topiramate tablets whole.
- Urge patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Advise patient to watch for decreased sweating and significantly increased body temperature, especially during hot weather, and to notify prescriber immediately if they occur.
- Tell patient to maintain adequate fluid intake to minimize the risk of developing kidney stones.
- Instruct patient to avoid alcohol use completely within 6 hours before and after taking topiramate.
- Advise female patient of possible breakthrough bleeding. If she takes an oral contraceptive, encourage her to use another form of contraception during therapy.
- Caution patient not to stop taking topiramate abruptly because seizures may occur. Instead, patient should expect drug to be withdrawn gradually if it must be discontinued.
- Instruct patient to seek immediate emergency care for blurred vision, other visual disturbances, or periorbital pain.
- Tell patient to notify prescriber if he develops changes in mental status, unexplained lethargy, or vomiting.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when topiramate therapy starts or dosage changes, and to report concerns at once to prescriber.
- Counsel female patient of childbearing age to use effective birth control, as topiramate therapy may cause cleft lip or palate as well as low body weight if the fetus is exposed to drug in utero.
- Urge woman who becomes pregnant while taking topiramate to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy.
- Alert mothers wishing to breastfeed that topiramate is excreted in breast milk, and to talk to prescriber before doing so while taking topiramate.

**torseמידe**

# Demadex

## Class and Category

*Pharmacologic class:* Loop diuretic

*Therapeutic class:* Antihypertensive, diuretic

*Pregnancy category:* B

## Indications and Dosages

- *To treat edema in heart failure*

### **TABLETS, I.V. INJECTION**

**Adults.** *Initial:* 10 to 20 mg daily (I.V. injected slowly over 2 min), adjusted by doubling, as prescribed, to achieve desired effect. *Maximum:* 200 mg daily.

- *To treat edema in chronic renal failure*

### **TABLETS, I.V. INJECTION**

**Adults.** *Initial:* 20 mg daily (I.V. injected slowly over 2 min), adjusted by doubling, as prescribed, to achieve desired effect. *Maximum:* 200 mg daily.

- *To treat ascites, alone or with amiloride or spironolactone*

### **TABLETS, I.V. INJECTION**

**Adults.** *Initial:* 5 to 10 mg daily (I.V. injected slowly over 2 min), adjusted by doubling, as needed to achieve desired effect. *Maximum:* 40 mg daily.

- *To manage hypertension*

## **TABLETS**

**Adults.** *Initial:* 5 mg daily, increased to 10 mg daily after 4 to 6 wk, if response is inadequate. *Maximum:* 10 mg daily.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	1 hr	1-2 hr	6-8 hr
I.V.	10 min	1 hr	6-8 hr

## **Mechanism of Action**

Blocks active chloride and sodium reabsorption in the ascending loop of Henle by promoting rapid excretion of chloride, sodium, and water. Torsemide also increases the production of renal prostaglandins, increasing the plasma renin level and renal vasodilation. As a result, blood pressure falls, reducing preload and afterload.

## **Contraindications**

Anuric patients; hepatic coma; hypersensitivity to torsemide, povidone, sulfonamides, or their components

## **Interactions**

### **DRUGS**

*ACE inhibitors, angiotensin receptor blockers, antihypertensives:* Additive hypotension; increased risk of renal impairment

*ACTH, corticosteroids:* Possibly increased risk of hypokalemia

*amiloride, spironolactone, triamterene:* Possibly counteracted torsemide-induced hypokalemia

*aminoglycoside antibiotics, ethacrynic acid*: Increased risk of ototoxicity

*amphotericin B*: Increased risk of nephrotoxicity and severe, prolonged hypokalemia or hypomagnesemia

*cholestyramine*: Possibly decreased absorption of orally administered torsemide

*cisplatin*: Increased risk of significant hypokalemia or hypomagnesemia, possibly permanent ototoxicity

*cortisone, fludrocortisone, hydrocortisone*: Increased risk of hypokalemia and sodium retention

*CYP2C9 inducers such as rifampin*: Decreased plasma concentrations of torsemide possibly decreasing effectiveness

*CYP2C9 inhibitors such as amiodarone, fluconazole, miconazole, oxandrolone*: Increased plasma concentrations of torsemide and possibly increased risk of adverse reactions

*CYP2C9 substrates such as celecoxib or substrates with a narrow therapeutic range, such as phenytoin, warfarin*:

Possibly decreased effectiveness and safety of these drugs

*digoxin*: Increased risk of arrhythmias and digitalis toxicity due to hypokalemia or hypomagnesemia

*indomethacin*: Possibly decreased antihypertensive and diuretic effects of torsemide and increased risk of renal failure

*lithium*: Possibly lithium toxicity

*metolazone, thiazide diuretics*: Increased risk of severe fluid and electrolyte loss

*nephrotoxic drugs such as aminoglycosides, cisplatin,*

*NSAIDs*: Increased risk of worsening renal function

*NSAIDs, salicylates*: Increased risk of nephrotoxicity and salicylate toxicity

*neuromuscular blockers*: Possibly increased neuromuscular blockade due to hypokalemia

*probenecid, other organic anion drugs*: Possibly decreased diuretic effect of torsemide

*quinidine and other ototoxic drugs*: Increased risk of ototoxicity

*radiocontrast agents*: Increased risk of renal toxicity

## ACTIVITIES

*alcohol use*: Additive diuresis and, possibly, dehydration

## Adverse Reactions

**CNS**: Confusion, dizziness, drowsiness, fatigue, headache, insomnia, lethargy, nervousness, paresthesia, restlessness, thirst, weakness

**CV**: Chest pain, **ECG abnormalities**, edema, **hypotension**, tachycardia

**EENT**: Dry mouth, hearing loss, ototoxicity, pharyngitis, rhinitis, tinnitus, visual impairment

**ENDO**: Hyperglycemia

**GI**: Abdominal pain, anorexia, constipation, diarrhea, elevated liver enzymes, indigestion, nausea, **pancreatitis**, vomiting

**GU**: **Azotemia**, elevated blood urea creatinine and nitrogen levels, oliguria, urinary frequency or retention, worsening renal function

**HEME**: Anemia, **leukopenia**, **thrombocytopenia**

**MS**: Muscle spasms, myalgia

**RESP**: Cough

**SKIN**: Photosensitivity, pruritus, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other**: Elevated uric acid levels, **hypocalcemia**, hypochloremic alkalosis, **hypokalemia**, **hypomagnesemia**, **hyponatremia**, hypovolemia, thiamine (vitamin B1) deficiency

# Nursing Considerations

- Inject I.V. torsemide slowly over 2 minutes. Flush I.V. line with normal saline solution before and afterward.
- Don't exceed 200 mg in a single I.V. dose of torsemide.
- Monitor patient's serum electrolyte levels and fluid intake and output to detect hypovolemia, because dehydration can worsen renal function, causing acute renal failure. Patients at higher risk include patients who are taking renin-angiotensin aldosterone inhibitors or other nephrotoxic drugs or who are salt-depleted. Expect to monitor renal function in patients who experience dehydration.
- Monitor patient with hepatic disease who has ascites or cirrhosis, because a sudden shift in fluid and electrolyte balance may precipitate hepatic coma. Diuretic therapy can also contribute to a variety of disorders such as azotemia, hypokalemia, hyponatremia, hypovolemia, or metabolic alkalosis in these patients, which can cause or worsen hepatic encephalopathy. Know that if this occurs, drug should be withheld or discontinued.

**WARNING** Expect torsemide-induced electrolyte imbalances, such as hypokalemia and hypomagnesemia, to increase the risk of toxicity and fatal arrhythmias in a patient who takes a digitalis glycoside. Hypokalemia also potentiates the neuromuscular blockade effects of nondepolarizing neuromuscular blockers.

## PATIENT TEACHING

- Advise patient to change position slowly to minimize the effects of orthostatic hypotension. Instruct patient to notify prescriber if fainting occurs.
- Tell patient to maintain an adequate fluid intake and to be aware that diarrhea, excessive perspiration, or vomiting can lower blood pressure, possibly causing fainting to occur. Instruct patient to notify prescriber if excessive fluid loss occurs.
- Warn patient not to take any over-the-counter NSAID drug without consulting prescriber first.

- Instruct patient to notify prescriber at once about drowsiness, dry mouth, hearing changes, lethargy, muscle pain, nausea, restlessness, thirst, vomiting, or weakness.
- Advise diabetic patient to monitor her blood glucose level often because drug may raise it.

## tramadol hydrochloride

**ConZip, Ultram, Ultram ER**

### Class, Category, and Schedule

*Pharmacologic class:* Opioid agonist

*Therapeutic class:* Opioid analgesic

*Pregnancy category:* C

*Controlled substance schedule:* IV

### Indications and Dosages

- *To relieve pain severe enough to require opioid-like treatment and for which alternative treatment options such as nonopioid analgesics or opioid combination products are inadequate or not tolerated*

#### **TABLETS**

**Adults with chronic pain not requiring rapid onset of analgesic effect.** *Initial:* 25 mg daily in morning, then titrated every 3 days in 25 mg increments in separate doses to reach 100 mg daily given as 25 mg four times daily. Then, if further analgesia is needed, total daily dose

increased by 50 mg every 3 days to reach 200 mg daily given as 50 mg four times daily.

**Adults requiring rapid pain relief.** 50 to 100 mg every 4 to 6 hr, as needed. *Maximum:* 400 mg daily.

- *To manage moderate to moderately severe chronic pain in patients who require around-the-clock treatment for an extended period of time*

## E.R. TABLETS

**Adults not currently treated with immediate-release form of tramadol.** 100 mg once daily, increased in 100-mg increments once daily every 5 days, as needed. *Maximum:* 300 mg once daily.

**Adults maintained on tramadol immediate-release form.** Dosage calculated using the 24-hr immediate-release dosage rounded down to the next lowest 100-mg increment. Dosage then adjusted as needed. *Maximum:* 300 mg once daily.

**DOSAGE ADJUSTMENT** For patients with creatinine clearance less than 30 ml/min, dosing interval increased to 12 hr with maximum daily dosage not to exceed 200 mg. For patients with cirrhosis, dosage reduced to 50 mg every 12 hr. For patients over 75 years of age, maximum dosage reduced to 300 mg daily.

Route	Onset	Peak	Duration
P.O. -immediate release	1 hr	2-3 hr	7-14 hr
P.O. -extended release	Unknown	12 hr	24 hr

## Mechanism of Action

Binds with mu receptors and inhibits the reuptake of norepinephrine and serotonin, which may account for tramadol's analgesic effect.

## Contraindications

Acute or severe bronchial asthma in the absence of resuscitative equipment or unmonitored setting, alcohol intoxication; children under the age of 12; excessive use of central-acting analgesics, hypnotics, opioids, or other psychotropic drugs; hypersensitivity to tramadol or its components; known or suspected gastrointestinal obstruction, including paralytic ileus; postoperative management in children ages 12 to 18 following adenoidectomy and/or tonsillectomy; significant respiratory depression; use within 14 days of MAO inhibitor therapy

## Interactions

### DRUGS

*alpha blockers, CYP2D6 and CYP3A4 inhibitors, linezolid, lithium, MAO inhibitors, St. John's wort, selective serotonin and norepinephrine reuptake inhibitors, tricyclic antidepressants, triptans:* Increased risk of serotonin syndrome

*amiodarone, cimetidine, clomipramine, CYP2D6 inhibitors (bupropion, fluoxetine, paroxetine), desipramine, fluphenazine, haloperidol, propafenone, quinidine, ritonavir, thioridazine:* Decreased analgesia, increased adverse effects of tramadol

*amitriptyline, amphetamines, antipsychotics, bupropion, cyclobenzaprine, dextroamphetamine, erythromycin, fluoxetine, ketoconazole, paroxetine, quinidine, MAO*

*inhibitors, naloxone, tricyclic antidepressants*: Increased risk of seizures

*antimigraine agents, cyclobenzaprine; dextromethorphan; dolasetron; granisetron; linezolid; MAO inhibitors; methylene blue; ondansetron; palonosetron; selected psychiatric drugs such as amoxapine, buspirone, lithium, mirtazapine, nefazodone, trazodone, vilazodone; selective serotonin reuptake inhibitors; serotonin-norepinephrine reuptake inhibitors; St. John's wort; tricyclic antidepressants; tryptophan*: Increased risk of serotonin syndrome

*benzodiazepines, CNS depressants, opioids, sedating antihistamines, tricyclic antidepressants*: Increased risk of severe respiratory depression and significant sedation and somnolence

*carbamazepine*: Increased tramadol metabolism

*CNS depressants such as barbiturates, benzodiazepines, opioid analgesics, phenothiazines, sedative-hypnotics, tranquilizers*: Additive CNS depression including coma, profound sedation, and respiratory depression

*CYP3A4 inducers such as carbamazepine, phenytoin, rifampin*: Decreased plasma concentration of tramadol and effectiveness

*CYP3A4 inhibitors such as azole antifungal agents, macrolide antibiotics, protease inhibitors*: Increased plasma concentration of tramadol and risk of adverse reactions

*general anesthetics*: Increased CNS and respiratory depression

*phenothiazines, rifampin*: Additive CNS depression, increased risk of seizures

*warfarin*: Possibly increased INR

## **ACTIVITIES**

*alcohol use:* Additive CNS depression and respiratory depression that may become severe

## Adverse Reactions

**CNS:** Agitation, anxiety, asthenia, depression, dizziness, emotional lability, euphoria, fatigue, fever, hallucinations, headache, hypertonia, hypoesthesia, insomnia, lethargy, nervousness, paresthesia, restlessness, rigors, **seizures**, **serotonin syndrome**, somnolence, **suicidal ideation**, tremor, vertigo, weakness

**CV:** Chest pain, orthostatic hypotension, **prolonged QT interval**, **torsades de pointes**, vasodilation

**EENT:** Blurred vision, dry mouth, nasal or sinus congestion, sore throat, vision changes

**ENDO:** **Adrenal insufficiency**, hot flashes

**GI:** Abdominal pain, anorexia, constipation, diarrhea, indigestion, nausea, vomiting

**GU:** Androgen deficiency, decreased libido, erectile dysfunction, impotence, infertility, lack of menstruation, urinary frequency, urine retention

**MS:** Arthralgia; back, limb, or neck pain

**RESP:** Cough, dyspnea, **respiratory depression (severe)**

**SKIN:** Diaphoresis, dermatitis, flushing, pruritus, rash

**Other:** **Anaphylaxis**, flu-like illness, physical and psychological dependence

## Nursing Considerations

- Be aware that tramadol shouldn't be given to patients with a history of anaphylactoid reactions to codeine or other opioids.
- Avoid giving tramadol to patients with acute abdominal conditions because it may mask evidence and disrupt assessment of the abdomen.

- Be aware that tramadol should not be given to children under the age of 12, children ages 12 to 18 who have undergone an adenoidectomy and/or tonsillectomy, and children who have other risk factors that may increase their sensitivity to the respiratory depressant effects of drug. Risk factors to be alert for include concomitant use of other medications that cause respiratory depression or conditions associated with hypoventilation, such as neuromuscular disease, obesity, obstructive sleep apnea, postoperative status, or severe pulmonary disease.
- Be aware that excessive use of tramadol may lead to abuse, addiction, misuse, overdose, and possibly death. Monitor patient's intake of drug closely and for evidence of physical dependence. Alert prescriber if patient has a history of dependence on other opioids. Be aware that a Risk Evaluation and Mitigation Strategy (REMS) is required before tramadol can be prescribed.
- Know that chronic maternal use of tramadol during pregnancy can result in neonatal opioid withdrawal syndrome (NOWS), which may be life-threatening if not recognized and treated appropriately. NOWS occurs when a newborn has been exposed to tramadol for a prolonged period while in utero.
- Use tramadol cautiously in patients who are taking antidepressant drugs or tranquilizers and in patients who use alcohol in excess or who suffer from depression or emotional disturbance.
- Watch for allergic reactions after giving first dose of tramadol, including angioedema, bronchospasm, pruritus, Stevens-Johnson syndrome, toxic epidermal necrolysis, and urticaria. Also watch for signs and symptoms of anaphylaxis, such as dyspnea and hypotension.

**WARNING** Monitor patient for respiratory depression that could become life-threatening quickly, especially when drug is initiated or dosage is increased. If patient develops respiratory depression, expect to give naloxone. Watch for seizures because naloxone may increase this risk. Take seizure precautions.

- Assess respiratory status often if patient has head injury or increased intracranial pressure because of possible increased carbon dioxide retention and CSF pressure, either of which may cause respiratory depression. Also, be aware that tramadol may constrict pupils, obscuring evidence of intracranial complications.

**WARNING** Watch for seizures in patients with epilepsy, a history of seizures, or an increased risk of seizures, such as those with alcohol or drug withdrawal, CNS infection, head injury, or metabolic disorder.

- Expect to taper tramadol rather than stopping it abruptly to avoid acute withdrawal symptoms such as anxiety, diarrhea, insomnia, nausea, pain, panic attacks, paresthesias, piloerection, rigors, sweating, tremor, and upper respiratory symptoms.

**WARNING** Know that many drugs may interact with tramadol to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with coordination, or vomiting. Notify prescriber at once because serotonin syndrome may be life-threatening. Be prepared to discontinue drug, if possible and ordered, and provide supportive care.

- Monitor patient for adrenal insufficiency. Although rare, it can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, or weakness. Notify prescriber if adrenal insufficiency is suspected and expect diagnostic testing to be done. If confirmed, expect to administer corticosteroids and wean patient off tramadol, if possible.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

**WARNING** Be aware that tramadol should only be used concomitantly with benzodiazepine therapy in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of tramadol to be limited. Monitor patient closely for signs and symptoms of a decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately

and provide emergency supportive care, as death may occur.

## **PATIENT TEACHING**

- Urge patient to follow prescribed dose limits and dosing intervals to prevent respiratory depression and seizures. Warn patient that excessive or prolonged use can lead to abuse, addiction, misuse, overdose, and possibly death.
- Instruct patient prescribed extended-release form to swallow tablet whole and not to chew, crush, or split tablet.
- Instruct patient to seek immediate emergency medical care and to stop taking tramadol if a serious allergic reaction occurs.
- Caution patient not to stop tramadol abruptly.
- Instruct patient to avoid hazardous activities until drug's CNS effects are known.
- Warn patient not to consume alcohol or take a benzodiazepine without prescriber knowledge, as severe respiratory depression can occur and may lead to death.
- Inform patient that long-term use of tramadol may decrease sex hormone levels, causing decreased libido, erectile dysfunction, impotence, infertility, or lack of menstruation. Encourage patient to report any symptoms to prescriber.
- Urge patient to notify prescriber about known, suspected, or intended pregnancy.
- Tell mothers wishing to breastfeed to consult prescriber before doing so, because if mother is an ultra-rapid metabolizer, infant could experience life-threatening respiratory depression.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes and to report concerns at once to prescriber.
- Tell patient to notify prescriber immediately if he develops any persistent, severe, sudden, or unusual adverse reactions.
- Instruct patient to inform all prescribers of tramadol therapy because of potential drug interactions.
- Caution patient to keep tramadol out of the reach of children because even one dose could result in a fatal overdose in a child.

- Warn patient that tramadol may cause severe constipation. Advise patient to maintain adequate hydration, increase fiber in diet, and to seek treatment instructions from prescriber if constipation occurs and is not relieved soon after onset.
- Instruct patient how to dispose of unused tramadol in accordance with local state guidelines and/or regulations.

## trazodone hydrochloride

**Desyrel, Oleptro**

### Class and Category

*Pharmacologic class:* Triazolopyridine derivative

*Therapeutic class:* Antidepressant

*Pregnancy category:* C

### Indications and Dosages

➤ *To treat major depression*

#### E.R. TABLETS

**Adults.** *Initial:* 150 mg once daily, increased by 75 mg daily every 3 days, as needed. *Maximum:* 375 mg daily.

#### TABLETS

**Adults.** 150 mg in divided doses daily following a meal or light snack, increased by 50 mg/day every 3 to 4 days. *Maximum:* 400 mg daily in divided doses.

---

**Route**

**Onset**

**Peak**

**Duration**

Route	Onset	Peak	Duration
P.O.	1-2 wk	Unknown	Unknown

## Mechanism of Action

Blocks serotonin reuptake along the presynaptic neuronal membrane, causing an antidepressant effect. Trazodone exerts an alpha-adrenergic blocking action and produces modest histamine blockade, causing a sedative effect. It also inhibits the vasopressor response to norepinephrine, which reduces blood pressure.

## Contraindications

Hypersensitivity to trazodone or its components, recovery from acute MI, use within 14 days of an MAO inhibitor including intravenous methylene blue and linezolid

## Interactions

### DRUGS

*aspirin, NSAIDs*: Possibly increased risk of bleeding  
*barbiturates and other CNS depressants*: Enhanced effect of CNS depressants

*carbamazepine*: Decreased trazodone level

*CYP3A4 inhibitors such as indinavir, ketoconazole, and ritonavir*: Possibly increased plasma trazodone levels with increased risk of adverse reactions

*digoxin, phenytoin*: Possibly increased blood levels of these drugs and increased risk of toxicity

*MAO inhibitors*: Increased serotonin effects

*serotonergic drugs*: Increased risk of serotonin syndrome

*warfarin*: Altered anticoagulation response

## ACTIVITIES

*alcohol use:* Increased CNS depression, risk of hypotension and respiratory depression

## Adverse Reactions

**CNS:** Abnormal coordination or dreams, agitation, anxiety, aphasia, ataxia, balance disorder, chills, confusion, **CVA**, dizziness, drowsiness, extrapyramidal symptoms, fatigue, hallucinations, headache, insomnia, light-headedness, memory impairment, migraine, nervousness, paresthesia, paranoid reaction, psychosis, **seizures**, **serotonin syndrome**, somnolence, stupor, **suicidal ideation**, syncope, tardive dyskinesia, tremor, vertigo, weakness

**CV:** **Arrhythmias**, **congestive heart failure**, edema, **hypotension**, orthostatic hypotension, palpitations, **prolonged QT interval**, vasodilation

**EENT:** Angle-closure glaucoma, blurred vision, diplopia, dry mouth

**ENDO:** Inappropriate ADH syndrome

**GI:** Abdominal pain, cholestasis, constipation, diarrhea, elevated bilirubin or liver enzymes, indigestion, jaundice, nausea, vomiting

**GU:** Anorgasmia; ejaculation disorders; decreased libido; priapism; urinary incontinence, retention, or urgency

**HEME:** **Hemolytic anemia**, leukocytosis

**MS:** Back pain, myalgia

**RESP:** **Apnea**, dyspnea

**SKIN:** Alopecia, hirsutism, night sweats, pruritus, psoriasis, rash, urticaria

**Other:** **Hyponatremia**

## Nursing Considerations

- Use trazodone cautiously in patients with cardiac disease because drug can cause arrhythmias.
- Give trazodone shortly after the patient has a meal or light snack to reduce nausea.
- Give larger portion of daily dose at bedtime if drowsiness occurs.
- Expect most patients who respond to trazodone to do so by the end of the second week of therapy.
- Closely monitor depressed patients for suicidal thoughts and tendencies. Notify prescriber if they occur, and take suicide precautions according to facility policy.

**WARNING** Monitor patient closely for serotonin syndrome exhibited by agitation, coma, diarrhea, hallucinations, hyperreflexia, hyperthermia, incoordination, labile blood pressure, nausea, tachycardia, and vomiting. Notify prescriber immediately because serotonin syndrome may be life-threatening and provide supportive care.

**WARNING** Be aware that serotonin syndrome in its most severe form may resemble neuroleptic malignant syndrome, which includes autonomic instability with possibly rapid changes in vital signs and mental status, or hyperthermia and muscle rigidity. Stop drug immediately and provide supportive care.

- Be aware that adverse CNS reactions usually improve after patient completes a few weeks of therapy.

**WARNING** Be aware that trazodone therapy may increase the risk of priapism.

## **PATIENT TEACHING**

- Urge patient to avoid taking trazodone on an empty stomach because doing so may increase the risk of dizziness or light-headedness.

- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute closure glaucoma. Encourage patient to have an eye exam before starting therapy to see if he is at risk.
- Caution patient to avoid potentially hazardous activities during therapy until nervous system effects have abated.
- Advise patient not to fast during trazodone therapy because of possible adverse CNS reactions.
- Instruct male patient to notify prescriber immediately about priapism.
- Caution patient not to take aspirin or nonsteroidal anti-inflammatory agents without first discussing use with the prescriber.
- Instruct patient not to stop trazodone therapy abruptly.
- Urge family and caregivers to watch patient closely for abnormal thinking or behavior or increased aggression or hostility. Emphasize importance of notifying prescriber about unusual changes.
- Advise women of childbearing age to notify prescriber if pregnancy occurs or is suspected. If pregnancy is confirmed, encourage patient to enroll in the pregnancy exposure registry.

**triamcinolone**

**triamcinolone acetonide**

**Azmacort, Kenalog-10, Kenalog-40,  
Nasacort Allergy 24 Hour, Zilretta**

**triamcinolone diacetate**

**triamcinolone hexacetonide**

**Aristospan**

## Class and Category

*Pharmacologic class:* Glucocorticoid

*Therapeutic class:* Corticosteroid

*Pregnancy category:* C (nasal and oral inhalation), Not classified

## Indications and Dosages

- *To prevent bronchospasm or provide long-term corticosteroid treatment to control asthma*

### ORAL INHALATION (AZMACORT)

**Adults and children age 12 and over.** *Initial:* 2 metered sprays (150 mcg) three times a day or four times a day.

Alternatively, 4 metered sprays (300 mcg) twice daily.

*Maximum:* 16 metered sprays (1,200 mcg) daily in divided doses.

**Children ages 6 to 11.** 1 to 2 metered sprays (75 to 150 mcg) three to four times daily. Alternatively, 2 to 4 metered sprays (150 to 300 mcg) twice daily. *Maximum:* 12 metered sprays (900 mcg) daily.

- *To treat a multitude of disorders exhibiting severe inflammation or need for immunosuppression*

### I.M. INJECTION (KENALOG-40)

**Adults.** 2.5 to 100 mg daily depending on specific disease entity being treated. Dosage adjusted as needed.

**Children.** *Initial:* 0.11 to 1.6 mg/kg daily in 3 or 4 divided doses. Dosage adjusted as needed.

### I.M. INJECTION (ARISTOCORT FORTE)

**Adults.** 3 to 48 mg daily depending on specific disease entity being treated. Dosage adjusted as needed.

**Children.** 0.11 to 1.6 mg/kg daily in three or four divided doses. Dosage adjusted as needed.

- *To relieve inflammation caused by acute gouty arthritis, acute nonspecific tenosynovitis, acute or subacute bursitis, epicondylitis, osteoarthritis, posttraumatic osteoarthritis, rheumatoid arthritis, and synovitis*

### **INTRA-ARTICULAR INJECTION (KENALOG-10)**

**Adults.** 2.5 to 5 mg for smaller joints and 5 to 15 mg for larger joints, as needed.

### **INTRA-ARTICULAR INJECTION (ARISTOCORT FORTE)**

**Adults.** 5 to 40 mg, and repeated, as needed 1 wk to 2 months.

### **INTRA-ARTICULAR INJECTION (ARISTOSPAN)**

**Adults.** 2 to 20 mg, repeated as prescribed every 3 to 4 wk, as needed.

- *To relieve osteoarthritis pain of the knee*

### **E.R. INTRA-ARTICULAR INJECTION (ZILRETTA)**

**Adults.** 32 mg injected once in the knee.

- *To relieve symptoms of perennial and seasonal allergic rhinitis*

### **NASAL INHALATION (NASACORT ALLERGY 24 HOUR)**

**Adults and children age 12 and over.** *Initial:* 110 mcg daily in 2 sprays (55 mcg each)/nostril.

**Children ages 6 to 11.** 110 mcg daily in 1 spray (55 mcg each)/nostril. *Maximum:* 220 mcg or 4 sprays daily.

**Children ages 2 to 5.** 110 mcg daily in 1 spray (55 mcg)/nostril.

Route	Onset	Peak	Duration
I.M.	24-48 hr	Unknown	1-6 wk
Inhalation-	12 hr	3-4 hr	Unknown
Intra- articular	Unknown	Unknown	Several wk
Nasal	Unknown	1.5-4 hr	Unknown

## Mechanism of Action

Inhibits the release of leukotrienes and prostaglandins, thus reducing immediate and late-phase allergic responses in chronic asthma. Triamcinolone also:

- decreases peribronchial edema and mucus secretion by inhibiting the binding of allergens to immunoglobulin E antibodies on the surface of mast cells, thereby inactivating the release of chemotactic substances
- decreases inflammation by interfering with leukocyte adhesion to capillary walls
- inhibits the release of leukocytic acid hydrolases, preventing macrophage accumulation at the infection site
- inhibits histamine and kinin release, preventing the formation of scar tissue.

## Incompatibilities

Don't mix triamcinolone hexacetonide with parenteral local anesthetics because precipitation can occur.

# Contraindications

Acute status asthmaticus (inhalation form), administered as an intrathecal injection, hypersensitivity to triamcinolone or its components, live-virus vaccine therapy, systemic fungal infection (except Aristocort Forte when administered as an intra-articular injection for localized joint conditions), idiopathic thrombocytopenic purpura (given as I.M. injection)

# Interactions

## DRUGS

*amphotericin B, ethacrynic acid, furosemide, thiazide diuretics:* Increased potassium-wasting effect, severe hypokalemia

*aspirin:* Increased blood salicylate level, increased risk of salicylate toxicity

*cholinesterase inhibitors:* Increased risk of severe muscle weakness in patients with myasthenia gravis

*CYP3A4 inhibitors such as atazanavir, clarithromycin, cobicistat-containing products, indinavir, itraconazole, ketoconazole, nefazodine, nelfinavir, ritonavir, saquinavir, telithromycin:* Decreased triamcinolone clearance, increased risk of adverse effects

*digitalis glycosides:* Increased risk of arrhythmias and digitalis toxicity

*estrogens:* Increased triamcinolone effects

*hepatic enzyme inducers such as barbiturates, carbamazepine, phenytoin, rifampin:* Increased triamcinolone metabolism with decreased effectiveness

*insulin, oral antidiabetic drugs:* Increased blood glucose level

*isoproterenol:* Increased risk of cardiotoxicity

*live-virus vaccines*: Decreased antibody response, increased risk of neurologic complications

*neuromuscular blockers*: Increased risk of hypokalemia and enhanced neuromuscular blockade

*NSAIDs*: Increased risk of adverse GI effects

*toxoids*: Decreased resistance to toxoids

## Adverse Reactions

**CNS**: Depression, dizziness, emotional lability, exacerbated psychosis, fatigue, headache, **increased intracranial pressure with papilledema (pseudotumor cerebri)**, insomnia, malaise, neuritis, neuropathy, paresthesia, personality changes, psychiatric disorders, restlessness, **seizures**, vertigo

**CV**: Edema, **heart failure**, hypertension

**EENT**: Altered sense of smell or taste, cataracts, dry mouth, epistaxis (nasal form), glaucoma, hoarseness, nasal congestion, nasal irritation (inhalation form), nasal septal perforation (nasal form), oropharyngeal candidiasis, pharyngitis, posterior subcapsular cataracts, rhinorrhea, secondary ocular infection, sinusitis, sneezing

**ENDO**: Cushing's syndrome, diabetes mellitus, growth retardation (children)

**GI**: Abdominal pain, constipation, diarrhea, dyspepsia, esophageal ulceration, gastritis, nausea, vomiting

**GU**: Altered motility and number of spermatozoa, cystitis, postmenopausal **vaginal hemorrhage**, renal disease, UTI, vaginitis

**MS**: Bone mineral density loss, bursitis, muscle wasting or weakness, myalgia, osteoporosis, tenosynovitis

**RESP**: **Asthma**, bronchitis, **bronchospasm** (inhalation form), chest congestion, dyspnea, increased cough

**SKIN**: Ecchymosis, petechiae (parenteral form), photosensitivity, pruritus, rash, striae, urticaria

**Other:** Anaphylaxis; angioedema; decreased resistance to infections; flu-like symptoms; herpes infection; hiccups; impaired wound healing; injection-site atrophy, induration, pain, soreness, and sterile abscess; moon face; weight gain

## Nursing Considerations

- Be aware that high doses of corticosteroids such as triamcinolone aren't recommended for patients with cranial trauma who don't require a corticosteroid for another condition because they increase risk of death.
- Know that triamcinolone should be administered with extreme caution, if at all, in patients who have active or quiescent tuberculosis infection of the respiratory tract, ocular herpes simplex, systemic parasitic or viral infection, or untreated bacterial or fungal infection, because this drug can make these infections worse.
- Use cautiously in patients with active or latent peptic ulcer, diverticulitis, fresh intestinal anastomoses, and nonspecific ulcerative colitis; there is increased risk of a perforation for these patients. Be aware that signs of peritoneal irritation following gastrointestinal perforation in patients receiving steroid therapy may be minimal or absent.
- Monitor patient with cirrhosis carefully for an enhanced drug effect because increased metabolism of steroids may occur in the presence of cirrhosis.
- Know that triamcinolone acetonide parenteral formulation with trade name Kenalog-40 can be administered I.M. Other parenteral triamcinolone acetonide forms should never be injected I.M. Shake I.M. suspension thoroughly before drawing it into syringe.
- Be aware that specialized training may be needed to administer parenteral triamcinolone.
- Don't administer parenteral forms of triamcinolone intravenously.

**WARNING** Know that drug should not be administered via the epidural or intrathecal route because severe neurologic adverse reactions may occur

- Know that drug should not be administered intra-articularly into an infected site, and injection into a previously infected joint is usually not

recommended.

- Be aware that triamcinolone may reactivate tuberculosis in patients who have a history of it.
- Monitor patient for hypersensitivity. Although rare, triamcinolone has caused anaphylaxis that ended in death. Notify prescriber immediately if hypersensitivity occurs; expect to discontinue triamcinolone therapy and provide emergency supportive care.
- Monitor patients for exposure to high doses, which may result in toxicity evidenced by life-threatening hypotension and metabolic acidosis.

**WARNING** Know that patients on corticosteroid therapy require an increased dosage of rapidly acting corticosteroids when unusual stress is anticipated, during the stressful event, and for a period after the stressful situation. Assess patient for signs and symptoms of adrenal insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, and weakness) during times of stress, such as infection, surgery, or trauma. Notify prescriber immediately if you detect these signs and symptoms because adrenal insufficiency may be life-threatening. Drug-induced secondary adrenocortical insufficiency may be minimized by gradual reduction of dosage.

- Be aware that, although rare, bone mineral density loss and osteoporosis may occur, which may increase risk of fractures, especially in patients on prolonged triamcinolone therapy.
- Adjust triamcinolone dosage, as prescribed, in patients with changes in thyroid status because metabolic clearance of corticosteroids is decreased in hypothyroid patients and increased in hyperthyroid patients.
- Assess patient for signs and symptoms of infection (abnormal symptoms in particular body system, fever, or malaise), because steroid therapy such as triamcinolone increases risk of susceptibility to infections, especially with higher dosages.

## **PATIENT TEACHING**

- Caution patient not to adjust dosage for prescription triamcinolone without consulting prescriber and to follow dosage recommendations when using an over-the-counter preparation.
- Teach patient how to administer nasal aerosols properly, using manufacturer's instructions, to avoid nasal irritation.
- Teach patient how to use nasal spray, including how to prime spray pump bottle before use. Caution patient not to get nasal spray in eyes. If this occurs, patient should rinse his eyes well with water.
- Inform patient that maximum benefit of triamcinolone therapy may not occur for up to 2 weeks.
- Advise patient to notify prescriber immediately if asthma fails to respond to inhaled drug; additional systemic therapy may be needed.
- Caution patient to avoid exposure to people who have chickenpox or measles, as well as other contagious infections, throughout triamcinolone therapy and for 12 months afterward.
- Advise patient to have periodic eye examinations during long-term therapy because triamcinolone can cause glaucoma or ocular nerve damage.

**triamterene**

**Dyrenium**

## **Class and Category**

*Pharmacologic class:* Potassium-sparing diuretic

*Therapeutic class:* Diuretic

*Pregnancy category:* B

## **Indications and Dosages**

- *To treat edema in cirrhosis, heart failure, and nephrotic syndrome, as well as edema secondary to hyperaldosteronism, idiopathic edema, and steroid-induced edema*

## CAPSULES

**Adults.** *Initial:* 100 mg twice daily after meals and adjusted as needed. *Maximum:* 300 mg daily.

Route	Onset	Peak	Duration
P.O.	2-4 hr	1 to several days	7-9 hr

## Mechanism of Action

Inhibits sodium reabsorption in distal convoluted tubules and cortical collecting ducts, causing sodium and water loss and enhancing potassium retention.

## Contraindications

Anuria, diabetic nephropathy or renal disease linked to renal insufficiency, hyperkalemia (potassium level of 5.5 mEq/L or more), hypersensitivity to triamterene or its components, severe hepatic dysfunction

## Interactions

### DRUGS

*ACE inhibitors, amiloride, angiotensin-II receptor antagonists, cyclosporine, heparin, potassium-containing drugs, potassium salts, potassium-sparing diuretics, potassium supplements:* Increased risk of hyperkalemia

*amantadine*: Decreased amantadine clearance, possibly amantadine toxicity

*antihypertensives*: Increased antihypertensive effect

*diuretics*: Increased diuretic effect

*folic acid*: Possibly antagonized action of folic acid

*indomethacin*: Increased risk of renal impairment

*lithium*: Increased risk of lithium toxicity

*NSAIDs*: Decreased diuretic effect of triamterene, increased risk of hyperkalemia

*oral antidiabetic drugs*: Altered blood glucose control

## Adverse Reactions

**CNS**: Dizziness, fatigue, headache, weakness

**EENT**: Dry mouth

**ENDO**: Hyperglycemia, **hypoglycemia**

**GI**: Diarrhea, jaundice, nausea, vomiting

**GU**: **Azotemia**, elevated BUN and serum creatinine levels, renal calculi

**SKIN**: Photosensitivity, rash

## Nursing Considerations

- Be aware that triamterene shouldn't be given to patient with creatinine clearance below 10 ml/min because this condition increases the risk of drug-induced hyperkalemia.
- Monitor serum potassium level during therapy, especially in patient with diabetes mellitus or renal impairment. Also monitor patient's BUN and serum creatinine levels to assess renal function and prevent hyperkalemia.
- Monitor patient for irregular heartbeat, which is usually the first sign of hyperkalemia. If you suspect hyperkalemia, obtain an ECG tracing, as ordered. A widened QRS complex or an arrhythmia requires prompt additional therapy.

- Monitor laboratory test results and watch for signs of metabolic or respiratory acidosis, which may occur suddenly in patient with cardiac disease or uncontrolled diabetes mellitus.
- Monitor patient's serum sodium and uric acid levels, as ordered, because triamterene may worsen preexisting hyponatremia and reduce uric acid clearance, increasing the risk of gout and hyperuricemia.
- Monitor CBC with differential because drug may increase the risk of megaloblastic anemia in patient with folic acid deficiency.

## PATIENT TEACHING

- Advise patient to take triamterene with food or milk.
- Instruct patient to avoid exposure to excessive heat or sunlight to prevent dehydration and, possibly, photosensitivity.
- Explain to patient with a history of gout that drug may increase the risk of attack.
- Advise patient to notify prescriber about ineffective diuresis and unexplained weight gain during therapy.

**triazolam**

**Halcion**

## Class, Category, and Schedule

*Pharmacologic class:* Benzodiazepine

*Therapeutic class:* Sedative-hypnotic

*Pregnancy category:* X

*Controlled substance schedule:* IV

## Indications and Dosages

- *To provide short-term management of insomnia*

## TABLETS

**Adults.** 0.125 to 0.25 mg at bedtime. *Maximum:* 0.5 mg daily (for patients with inadequate response to usual dose).

***DOSAGE ADJUSTMENT*** For elderly or debilitated patients, initial dosage not to exceed 0.125 mg at bedtime and maximum dosage limited to 0.25 mg daily.

Route	Onset	Peak	Duration
P.O.	15-30 min	Unknown	Unknown

## Mechanism of Action

Potentiates effects of the inhibitory neurotransmitter gamma-aminobutyric acid, which increases inhibition of the ascending reticular activating system and produces varying levels of CNS depression, including anticonvulsant activity, coma, hypnosis, sedation, and skeletal muscle relaxation.

## Contraindications

Concurrent therapy with azoles such as fluconazole, itraconazole, ketoconazole, or nefazodone, and selected HIV protease inhibitors such as indinavir, lopinavir, nelfinavir, ritonavir, or saquinavir; hypersensitivity to triazolam, other benzodiazepines, or their components; pregnancy

## Interactions

## DRUGS

*anxiolytics, barbiturates, brompheniramine, carbinoxamine, cetirizine, chlorpheniramine, clemastine, cyproheptadine, diphenhydramine, doxylamine, general anesthetics, methdilazine, opioid analgesics, other benzodiazepines and CNS depressants, phenothiazines, promethazine, sedating antihistamines, sedative-hypnotics, tramadol, tricyclic antidepressants, trimeprazine: Increased sedation, respiratory depression that could become severe azoles such as itraconazole, ketoconazole, or nefazodone; selected HIV protease inhibitors such as indinavir, lopinavir, nelfinavir, ritonavir, or saquinavir: Possibly increased plasma triazolam levels and increased risk of adverse reactions cimetidine, diltiazem, disulfiram, erythromycin, probenecid, verapamil: Increased sedation flumazenil: Increased risk of withdrawal symptoms oral contraceptives: Increased blood triazolam level*

## **FOODS**

*grapefruit juice: Increased blood triazolam level and sedation*

## **ACTIVITIES**

*alcohol use: Increased sedation, respiratory depression that could become severe*

## **Adverse Reactions**

**CNS:** Anxiety, ataxia, complex behaviors (such as sleep driving), confusion, depression, dizziness, drowsiness, fatigue, headache, insomnia, nightmares, syncope, talkativeness, tremor, vertigo

**EENT:** **Throat tightness**

**GI:** Nausea, vomiting

**RESP:** Dyspnea

**Other:** **Anaphylaxis, angioedema**, physical and psychological dependence

## Nursing Considerations

- Be aware that triazolam shouldn't be discontinued abruptly, even after only 1 to 2 weeks of therapy. Doing so can cause withdrawal symptoms, including abdominal cramps, confusion, depression, diaphoresis, hyperacusis, insomnia, irritability, nausea, nervousness, paresthesia, perceptual disturbances, photophobia, tachycardia, tremor, and vomiting.

**WARNING** Assess patient for signs of physical and psychological dependence, and notify prescriber if they occur.

- Monitor patient's ABG results and respiratory depth and rate, as appropriate, because drug may worsen ventilatory failure in patient with pulmonary disease, such as respiratory depression, severe COPD, or sleep apnea. Use drug cautiously in patients with acute intermittent porphyria, myasthenia gravis, and severe renal impairment because it may aggravate these conditions.
- Take safety precautions for elderly patients because triazolam may impair cognitive and motor function and increase the risk for falls.
- Use drug cautiously in patients with advanced Parkinson's disease because it may worsen cognition, coordination, and psychosis.

**WARNING** Monitor patient closely for hypersensitivity reactions such as dyspnea, nausea, swelling, throat tightness, and vomiting. If present, stop triazolam immediately, notify prescriber, and provide supportive care.

**WARNING** Be aware that opioids should only be used concomitantly with benzodiazepine therapy like triazolam in patients for whom other treatment options are inadequate. If prescribed together, expect dosing

and duration of the opioid to be limited. Monitor patient closely for signs and symptoms of a decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

## **PATIENT TEACHING**

- Instruct patient to take triazolam exactly as prescribed and not to stop taking it abruptly because of the risk of having withdrawal symptoms.
- Instruct patient to stop taking triazolam and seek emergency care if she has abnormal swelling, nausea, throat tightness, trouble breathing, or vomiting.
- Advise patient that drug may cause abnormal behaviors during sleep, such as driving a car, eating, having sex, or talking on the phone without any recall of the event. If family notices any such behavior or patient sees evidence of such behavior upon awakening, the prescriber should be notified.
- Caution patient about possible drowsiness during therapy and to avoid performing hazardous activities, if present.
- Urge patient to avoid alcohol consumption and opioid use because these increase drug's sedative effects, including respiratory depression which can become severe, and risk of abnormal behaviors, such as sleep driving.
- Advise patient to notify prescriber about excessive drowsiness, known or suspected pregnancy, and nausea.
- Instruct patient to inform all prescribers of triazolam use, especially when pain medication may be prescribed.

**trospium chloride**

**Sanctura, Sanctura XR**

## Class and Category

*Pharmacologic class:* Antimuscarinic

*Therapeutic class:* Bladder antispasmodic

*Pregnancy category:* C

## Indications and Dosages

- *To treat overactive bladder with symptoms of urge urinary incontinence, urgency, and urinary frequency*

### **TABLETS**

**Adults.** 20 mg twice daily 1 hr before meals or on empty stomach.

***DOSAGE ADJUSTMENT*** For patients with severe renal insufficiency (creatinine clearance less than 30 ml/min/1.73 m<sup>2</sup>) and patients age 75 or over, dosage reduced to 20 mg daily at bedtime.

### **E.R. CAPSULES**

**Adults.** 60 mg daily in the morning, 1 hr before a meal or on empty stomach.

Route	Onset	Peak	Duration
P.O.	Unknown	5–6 hr	Unknown

## Mechanism of Action

Antagonizes the effect of acetylcholine on muscarinic receptors in the bladder. Trospium's parasympatholytic action reduces the tonus of smooth muscle in the bladder. These actions increase maximum cystometric bladder capacity and volume with the first detrusor contraction,

which relieves the sensation of frequency and urgency and enhances bladder control.

## Contraindications

Gastric retention, hypersensitivity to trospium or its components, uncontrolled angle-closure glaucoma, urine retention

## Interactions

### DRUGS

*anticholinergics*: Increased frequency or severity of adverse effects; possibly reduced absorption of trospium

*digoxin, metformin, morphine, pancuronium, procainamide*: Possibly increased plasma concentration of all these drugs as well as trospium

### ACTIVITIES

*alcohol use*: Possibly increased drowsiness

## Adverse Reactions

**CNS**: Confusion, delirium, dizziness, drowsiness, fatigue, fever, hallucinations, headache, insomnia, light-headedness, syncope

**CV**: Chest pain, **hypertensive crisis**, palpitations, tachycardia

**EENT**: Blurred vision; dry eyes, mouth, or throat; visual abnormalities

**GI**: Abdominal distention or pain, constipation, flatulence, gastritis, indigestion, vomiting

**GU**: Urine retention

**MS:** Rhabdomyolysis

**SKIN:** Decreased sweating, dry skin, flushing, rash,

Stevens-Johnson syndrome

**Other:** Anaphylaxis, angioedema

## Nursing Considerations

- Use trospium cautiously in patients with intestinal atony, myasthenia gravis, or ulcerative colitis, because drug may decrease GI motility; patients with significant bladder outflow obstruction because drug may cause urine retention; patients with hepatic impairment because drug's effects on the liver are unknown; and patients with renal impairment because drug excretion may be impaired.
- Monitor elderly patients carefully, especially those age 75 or over, for adverse reactions because elderly patients have an increased risk of trospium-induced adverse reactions.
- Monitor patient for anticholinergic central nervous system adverse effects such as confusion, dizziness, hallucinations, and somnolence. If present, notify prescriber and expect a dose reduction or drug to be discontinued.

## PATIENT TEACHING

- Instruct patient to take trospium on an empty stomach or at least 1 hour before eating because food delays its absorption.
- Caution patient to avoid performing activities in a warm or hot environment because sweating may be delayed, which could cause a sudden increase in body temperature and heatstroke.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Inform patient that alcohol may increase the risk of drowsiness; urge patient to limit or abstain from alcoholic beverages while taking trospium.
- Emphasize importance of reporting allergic reactions, including swelling of her face, lips, throat, or tongue; stopping trospium therapy; and seeking emergency medical care immediately.
- Advise patient to notify prescriber if he develops confusion, dizziness, hallucinations, or somnolence, as dosage may have to be altered or drug discontinued.

## U V W

### umeclidinium

**Incruse Ellipta**

### Class and Category

*Pharmacologic class:* Anticholinergic

*Therapeutic class:* Bronchodilator

*Pregnancy category:* C

### Indications and Dosages

- *To provide long-term maintenance treatment of airflow obstruction in chronic obstructive pulmonary disease (COPD), including chronic bronchitis and/or emphysema*

### ORAL INHALATION

**Adults.** 62.5 mcg (1 inhalation) daily. *Maximum:* 62.5 mcg in a 24-hr period.

### Mechanism of Action

Inhibits the muscarinic M<sup>3</sup> receptor in smooth muscle to cause bronchodilation.

# Contraindications

Hypersensitivity to umeclidinium or its components, severe hypersensitivity to milk proteins

# Interactions

## DRUGS

*anticholinergics*: Possibly additive effects

# Adverse Reactions

*CNS*: Depression, dizziness, headache, vertigo

*CV*: **Atrial fibrillation**, **idioventricular rhythm**, supraventricular extrasystole, tachycardia

*EENT*: Blurred vision, eye pain, nasopharyngitis, pharyngitis, rhinitis, worsening of narrow-angle glaucoma

*GI*: Abdominal pain (upper), diarrhea, dyspepsia, nausea

*GU*: Dysuria, urinary retention, UTI, worsening of urinary retention

*MS*: Arthralgia; back, extremity, or neck pain; myalgia

*RESP*: Cough, **paradoxical bronchospasm**, respiratory tract infection

*SKIN*: Pruritus, rash, urticaria

*Other*: **Anaphylaxis**, **angioedema**

# Nursing Considerations

- Know that umeclidinium should not be initiated in patients who are experiencing a rapidly deteriorating or potentially life-threatening episode of COPD.
- Do not administer umeclidinium for relief of acute symptoms. Drug is not a rescue inhaler. Instead, acute symptoms should be treated with an inhaled, short-acting beta<sub>2</sub>-agonist, as ordered.

- Monitor patient for hypersensitivity reactions such as anaphylaxis, pruritus, rash, swelling in any area of the body, or urticaria. Expect drug to be discontinued if present. Be prepared to treat according to protocol standards. Know that patients with a severe milk protein allergy should not receive umeclidinium therapy because after inhaling other powder products containing lactose, some patients with a severe milk protein allergy have developed serious hypersensitivity reactions.
- Use with caution in patients with narrow-angle glaucoma or urinary retention because these conditions may worsen with umeclidinium therapy.

**WARNING** Monitor patient's respiratory status for paradoxical bronchospasm. Because of its life-threatening nature, notify prescriber immediately, withhold umeclidinium, and prepare to treat patient with an inhaled, short-acting bronchodilator, as ordered. If bronchospasm develops during umeclidinium therapy, expect drug to be permanently discontinued.

## PATIENT TEACHING

- Tell patient to take umeclidinium at about the same time every day and not to use more than once in a 24-hour period.
- Remind patient that umeclidinium cannot be used to relieve acute symptoms of COPD. Instead, tell patient to treat acute symptoms with a prescribed inhaled, short-acting beta<sub>2</sub> agonist such as albuterol, as prescribed.
- Teach patient how to use the inhaler.
- Urge patient to notify prescriber if her symptoms worsen, if umeclidinium becomes less effective, or if she needs more inhalations of her prescribed short-acting beta<sub>2</sub>-agonist than usual. This may indicate that patient's condition is worsening.
- Inform patient that drug may cause paradoxical bronchospasms. If present, tell patient to discontinue drug and notify prescriber.
- Tell patient to notify prescriber immediately if she develops blurred vision; colored images in association with red eyes; eye discomfort, pain, or visual halos.

- Advise patient to notify prescriber immediately if she develops any difficulty passing urine or painful urination, especially if she has a bladder-neck obstruction or if, in a male patient, prostatic hyperplasia is present.
- Instruct patient not to stop taking umecclidinium without prescriber knowledge, because symptoms may recur.

## ursodiol

(ursodeoxycholic acid)

**Actigall, Urso Forte, URSO 250,  
Ursofalk (CAN)**

### Class and Category

*Pharmacologic class:* Bile acid

*Therapeutic class:* Bile salt replenisher, cholelitholytic

*Pregnancy category:* B

### Indications and Dosages

- *To prevent gallstone formation in obese patients during rapid weight loss*

#### **CAPSULES (ACTIGALL, URSO FORTE)**

**Adults and adolescents.** 300 mg twice daily.

- *To dissolve gallstones*

#### **CAPSULES (ACTIGALL, URSO FORTE)**

**Adults and adolescents.** 8 to 10 mg/kg daily in divided doses twice daily or three times a day.

➤ *To treat primary biliary cirrhosis*

## **TABLETS (URSO 250)**

**Adults.** 13 to 15 mg/kg daily in two to four divided doses.

## **Mechanism of Action**

Suppresses biliary secretion, hepatic synthesis, and intestinal reabsorption of cholesterol. Prolonged use promotes dissolution of gallstones.

## **Contraindications**

Acute cholangitis; gallstone complications (such as biliary GI fistula; biliary obstruction; calcified, radiopaque, or radiotranslucent bile-pigment gallstones; cholecystitis; pancreatitis); hypersensitivity to ursodiol, other bile acids, or their components

## **Interactions**

### **DRUGS**

*aluminum-containing antacids, cholestyramine, colestipol:* Decreased absorption and therapeutic effects of ursodiol  
*clofibrate, estrogens, neomycin, oral contraceptives, progestins:* Interference with ursodiol's therapeutic effects; increased risk of gallstone formation

### **FOODS**

*any foods:* Increased dissolution of drug

# Adverse Reactions

**CNS:** Anxiety, asthenia, depression, dizziness, fatigue, fever, headache, malaise, sleep disturbance

**CV:** Chest pain, hypertension, peripheral edema

**ENDO:** Hyperglycemia

**EENT:** **Laryngeal edema**, metallic taste, rhinitis, stomatitis

**GI:** Abdominal discomfort or pain, cholecystitis, constipation, diarrhea, elevated liver enzymes, esophagitis, flatulence, indigestion, jaundice, nausea, peptic ulcer, vomiting

**GU:** Elevated creatinine level

**HEME:** **Leukopenia, thrombocytopenia**

**MS:** Arthralgia, back pain, myalgia

**RESP:** Cough

**SKIN:** Alopecia, diaphoresis, dry skin, pruritus, rash, urticaria

**Other:** **Angioedema**

# Nursing Considerations

- Administer ursodiol with food to increase drug dissolution.
- Give aluminum-containing antacids, cholestyramine, and colestipol at least 1 hour before or 4 hours after ursodiol because they may decrease drug's effects.
- Monitor patient's liver enzymes every month for 3 months after ursodiol therapy is begun and then every 6 months thereafter, as ordered. If elevation occurs, notify prescriber as drug may have to be discontinued.
- Expect drug to be discontinued if gallstones haven't partially dissolved after 12 months of therapy.
- If patient inadvertently takes too much ursodiol, diarrhea will most likely result and may warrant systemic treatment.

# PATIENT TEACHING

- Tell patient to take ursodiol with meals.
- Urge patient to take aluminum-containing antacids at least 1 hour before or 4 hours after ursodiol to support absorption.
- Urge patient to notify prescriber immediately if evidence of acute cholecystitis develops, such as acute right-upper-quadrant abdominal pain.
- Inform patient that he may need to take ursodiol for a prolonged period before gallstones dissolve.
- Advise diabetic patient to monitor blood glucose levels during therapy because ursodiol may alter blood glucose control.

# ustekinumab

## Stelara

### Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Immunomodulator

*Pregnancy category:* B

### Indications and Dosages

- *To treat moderate to severe plaque psoriasis in patients who are candidates for phototherapy or systemic therapy*

### SUBCUTANEOUS INJECTION

**Adults and children ages 12 to 18 weighing more than 100 kg (220 lb).** *Initial:* 90 mg followed by 90 mg 4 wk

later and then 90 mg every 12 wk.

**Adults weighing 100 kg (220 lb) or less.** *Initial:* 45 mg followed by 45 mg 4 wk later and then 45 mg every 12 wk.

**Children ages 12 to 18 weighing 60 kg (132 lb) to 100 kg (220 lb).** *Initial:* 45 mg, followed by 45 mg 4 wk later, and then 45 mg every 12 wk.

**Children ages 12 to 18 weighing less than 60 kg (132 lb).** 0.75 mg/kg, followed by 0.75 mg/kg 4 wk later and then 0.75 mg/kg every 12 wk.

- *To treat active psoriatic arthritis as monotherapy or in combination with methotrexate.*

## **SUBCUTANEOUS INJECTION**

**Adults.** *Initial:* 45 mg, followed by 45 mg 4 wk later, and then 45 mg every 12 wk.

***DOSAGE ADJUSTMENT*** For patients who weigh more than 100 kg (220 lb) and also have coexistent moderate to severe plaque psoriasis in addition to psoriatic arthritis, initial dosage increased to 90 mg followed by 90 mg 4 wk later, and then 90 mg every 12 wk.

- *To treat moderate to severe active Crohn's disease in patients who have either failed or were intolerant of treatment with corticosteroids or immunomodulators but never failed treatment with a tumor necrosis factor (TNF) blocker or failed or were intolerant of treatment with one or more TNF blockers*

## **I.V. INFUSION**

**Adults who weigh more than 85 kg (187 lb).** *Initial:* 520 mg as a single infusion infused over at least 60 min.

**Adults who weigh more than 55 kg (121 lb) but less than 86 kg (189 lb).** *Initial:* 390 mg as a single infusion infused over at least 60 min.

**Adults who weigh 55 kg (121 lb) or less.** *Initial:* 260 mg as a single infusion infused over at least 60 min.

## SUBCUTANEOUS INJECTION

**Adults.** *Maintenance:* 90 mg 8 wk after initial intravenous dose, then every 8 wk thereafter.

Route	Onset	Peak	Duration
SubQ	Unknown	7-13.5 days	Unknown
I.V.	Unknown	Unknown	Unknown

## Mechanism of Action

Binds to p40 protein subunit used by interleukin (IL)-12 and IL-23 cytokines. These specific cytokines are involved in inflammatory and immune responses, such as natural killer cell activation and CD4<sup>+</sup> T-cell differentiation and activation. By disrupting signaling mediated by IL-12 and IL-23, signs and symptoms caused by inflammatory and immune responses are diminished or relieved.

## Contraindications

Hypersensitivity to ustekinumab or its components

## Interactions

### DRUGS

*cytochrome P-450 substrates such as cyclosporine, theophylline, warfarin:* Possibly altered effects or blood levels of these drugs when ustekinumab is started or stopped

*live-virus vaccines*: Increased risk of adverse vaccine effects

## Adverse Reactions

**CNS:** Depression, dizziness, fatigue, headache, **reversible posterior leukoencephalopathy syndrome**

**ENDO:** Nasopharyngitis, pharyngolaryngeal pain

**GI:** Diarrhea, diverticulitis, gastroenteritis

**GU:** UTI

**MS:** Back pain, myalgia, osteomyelitis

**RESP:** Pneumonia, upper respiratory tract infection

**SKIN:** Cellulitis, erythrodermic psoriasis, pruritus, pustular psoriasis, rash, urticaria

**Other:** **Anaphylaxis, angioedema**, anti-ustekinumab antibodies, injection-site reactions (bruising, erythema, hemorrhage, induration, irritation, pain, pruritus, swelling), **malignancies (breast, colorectal, head and neck, kidney, melanoma and nonmelanoma disorders of skin, prostate, or thyroid)**, serious infection, including bacterial, fungal, and viral infections and reactivation of latent infections

## Nursing Considerations

- Make sure patient has a tuberculin skin test before therapy starts. If skin test is positive, treatment of latent tuberculosis should start before ustekinumab therapy starts. Also expect antituberculosis therapy to start if patient has a history of latent or active tuberculosis but adequate therapy can't be confirmed or if patient has a negative test for latent tuberculosis but has risk factors for tuberculosis.
- Make sure patient is current with all immunizations before starting ustekinumab therapy because patient shouldn't receive live vaccines during treatment. BCG vaccines shouldn't be given for 1 year before or after ustekinumab therapy.

- Use caution when administering ustekinumab to a patient undergoing allergen immunotherapy because drug may decrease the protective effect of allergen immunotherapy which in turn may increase the risk of an allergic reaction to a dose of allergen immunotherapy.
- Use ustekinumab cautiously in patients with recurrent infection or increased risk of infection and in patients who live in regions where histoplasmosis and tuberculosis are endemic.

**WARNING** Know that if patient has evidence of an active infection when drug is prescribed, therapy shouldn't start until infection has been treated. Monitor all patients for infection during therapy, especially those receiving immunosuppressants. Be on the alert for cough, dyspnea, and interstitial infiltrates following one to three doses that may suggest pneumonia has developed. If a serious infection, an opportunistic infection, or sepsis develops, expect prescriber to stop ustekinumab and start appropriate antimicrobial therapy.

- Be aware that patients with a history of cancer or who have genetic deficiencies in IL-12 or IL-23 should be thoroughly evaluated before ustekinumab therapy starts because various cancers have occurred in patients being treated with ustekinumab. Monitor patients throughout therapy for persistent, severe, or unusual signs and symptoms.
- Give ustekinumab subcutaneously by using a 27G, half-inch needle into gluteal region, thighs, upper arms, or any quadrant of abdomen. Rotate sites, and avoid areas that are bruised, erythematous, indurated, or tender.
- Note that needle cover on prefilled syringe used for subcutaneous injections contains a latex derivative and shouldn't be handled by persons with a latex allergy.
- Prepare intravenous infusion by first determining the number of ustekinumab vials needed based on patient's weight (each 26-ml vial contains 130 mg of ustekinumab). Withdraw, and then discard a volume of the 0.9% sodium chloride injection, USP, from the 250-ml infusion bag equal to the volume of drug to be added. Withdraw the dose from each vial needed and add it to the 250-ml infusion bag. The final volume in the infusion bag should be 250 ml. Gently mix. Diluted solution may be stored for up to 4 hours prior to infusion.

- Use only an infusion set for intravenous administration that has an in-line, sterile, nonpyrogenic, low protein-binding filter (pore size 0.2 micrometer). Do not infuse ustekinumab concomitantly in the same intravenous line with other agents. Infuse diluted solution to be given intravenously over at least 1 hour.
- Know that comparison of the incidence of antibodies to ustekinumab with the incidence of antibodies to other products may be misleading.
- Monitor patient for hypersensitivity reactions that could become life threatening. At first sign of hypersensitivity, notify prescriber, expect drug to be discontinued, and provide supportive care.
- Monitor patient for confusion, headache, seizures, and vision disturbances, which may signal reversible posterior leukoencephalopathy syndrome, a rare neurologic disorder that may occur with ustekinumab therapy. If present, notify prescriber, discontinue ustekinumab therapy, and provide appropriate treatment, as ordered.
- Inspect patient's skin regularly for evidence of abnormalities because rapid appearance of multiple cutaneous squamous cell carcinoma has occurred in patients who had preexisting risk factors for nonmelanoma skin cancer. Patients who are over 60 years of age, have a medical history of prolonged immunosuppressant therapy, and those with a history of psoralen plus ultraviolet radiation using UVA bands (PUVA) treatment should be closely monitored.

## **PATIENT TEACHING**

- Inform patient that treatment must be supervised by a healthcare professional.
- Teach patient how to administer the drug subcutaneously, if self-administration is ordered by prescriber.
- Inform patient that tuberculosis may occur during ustekinumab therapy. Instruct him to report low-grade fever, persistent cough, or wasting or weight loss to prescriber.
- Teach patient to recognize and report evidence of infection; drug may need to be stopped. Advise patient to avoid people with infections and to have all prescribed laboratory tests performed.
- Inform patient that the risk of developing certain kinds of cancer is higher in patients taking ustekinumab. Emphasize importance of follow-up visits and reporting any persistent, sudden-onset, or unusual signs or symptoms.

- Caution against receiving live-virus vaccines while taking ustekinumab; doing so may adversely affect the immune system.
- Urge patient to inform all healthcare providers about ustekinumab use and to inform prescriber about all OTC medications being taken, including herbal remedies and mineral and vitamin supplements.
- Encourage any woman who becomes pregnant while receiving ustekinumab to enroll in the pregnancy registry.

## valproic acid

**Alti-Valproic (CAN), Depakene, Stavzor**

## valproate sodium

**Depacon**

## divalproex sodium

**Depakote, Depakote ER, Depakote Sprinkle, Epival (CAN)**

## Class and Category

*Pharmacologic class:* Carboxylic acid derivative

*Therapeutic class:* Anticonvulsant

*Pregnancy category:* D (epilepsy, manic episodes associated with bipolar disorder), X (prevention of migraine headaches)

## Indications and Dosages

- *To treat as monotherapy or as adjunct complex partial seizures that occur in isolation or associated with other types of seizures*

### **CAPSULES, DELAYED-RELEASE SPRINKLE CAPSULES, DELAYED-RELEASE TABLETS, SYRUP, I.V. INFUSION (VALPROIC ACID, VALPROATE SODIUM, DIVALPROEX SODIUM)**

**Adults and children age 10 and over.** *Initial:* 10 to 15 mg/kg/day, increased by 5 to 10 mg/kg daily every wk, as needed. *Maximum:* 60 mg/kg daily.

- *To treat as monotherapy or as adjunct simple and complex absence seizures*

### **CAPSULES, DELAYED-RELEASE SPRINKLE CAPSULES, DELAYED-RELEASE TABLETS, SYRUP, I.V. INFUSION (VALPROIC ACID, VALPROATE SODIUM, DIVALPROEX SODIUM)**

**Adults.** *Initial:* 15 mg/kg/day, increased by 5 to 10 mg/kg daily every wk, as needed. *Maximum:* 60 mg/kg/day.

***DOSAGE ADJUSTMENT*** For adults being converted from immediate-release divalproex tablets to delayed-release tablets, dosage increased by 8% to 20% more than total daily dose of immediate-release tablets and given once daily.

- *To treat acute manic phase of bipolar disorder*

### **DELAYED-RELEASE TABLETS (DIVALPROEX SODIUM), DELAYED-RELEASE CAPSULES (STAVZOR)**

**Adults.** *Initial:* 750 mg daily in divided doses. *Maximum:* 60 mg/kg daily.

## **EXTENDED-RELEASE TABLETS (DIVALPROEX SODIUM)**

**Adults.** *Initial:* 25 mg/kg/day once daily, increased as rapidly as possible to achieve therapeutic dose. *Maximum:* 60 mg/kg/day.

► *To prevent migraine headache*

## **DELAYED-RELEASE TABLETS (DIVALPROEX SODIUM), DELAYED-RELEASE CAPSULES (STAVZOR)**

**Adults.** *Initial:* 250 mg every 12 hr, increased as needed. *Maximum:* 1 g daily.

## **EXTENDED-RELEASE TABLETS (DIVALPROEX SODIUM)**

**Adults.** *Initial:* 500 mg daily for 1 wk, increased, as needed, up to 1 g daily. *Maximum:* 1 g daily.

## **Mechanism of Action**

May decrease seizure activity by blocking reuptake of gamma-aminobutyric acid (GABA), the most common inhibitory neurotransmitter in the brain. GABA suppresses the rapid firing of neurons by inhibiting voltage-sensitive sodium channels.

## **Contraindications**

Hepatic impairment; hypersensitivity to valproic acid, valproate sodium, divalproex sodium, or their components;

mitochondrial disease caused by POLG mutations;  
pregnancy or women of childbearing age who are not using  
effective contraception (for prevention of migraine  
headaches); urea cycle disorders

## Interactions

### DRUGS

*aspirin*: Increased valproic acid level with possible  
increased risk of adverse reactions

*aspirin, heparin, NSAIDs, oral anticoagulants,  
thrombolytics*: Increased inhibition of platelet aggregation  
and risk of bleeding

*barbiturates, primidone*: Increased blood levels of both  
drugs, additive CNS effects

*carbamazepine, phenobarbital, phenytoin, primidone,  
rifampin, ritonavir*: Possibly decreased valproic acid  
effectiveness

*carbapenem antibiotics (ertapenem, imipenem,  
meropenem)*: Reduced serum valproic acid level, causing  
loss of seizure control

*chlorpromazine*: Increased trough plasma levels of  
valproate

*cholestyramine*: Decreased bioavailability of valproic acid

*clonazepam*: Increased risk of absence seizures

*CNS depressants*: Increased CNS depression

*diazepam*: Inhibited diazepam metabolism

*estrogen-containing hormonal contraceptives*: Possibly  
increased clearance of valproate, which may decrease  
effectiveness and increase risk of seizures

*ethosuximide*: Unpredictable blood ethosuximide level

*felbamate*: Impaired valproic acid metabolism and  
increased valproate level

*haloperidol, loxapine, MAO inhibitors, phenothiazines, thioxanthenes, tricyclic antidepressants*: Increased CNS depression, lowered seizure threshold  
*lamotrigine*: Decreased lamotrigine clearance  
*mefloquine*: Decreased blood levels of divalproex, valproate sodium, and valproic acid; increased risk of seizures  
*phenytoin*: Increased risk of phenytoin toxicity, loss of seizure control  
*propofol*: Possibly increased blood levels of propofol  
*rufinamide*: Increased rufinamide concentrations  
*topiramate*: Increased risk of hyperammonemia with or without encephalopathy

## ACTIVITIES

*alcohol use*: Additive CNS depression

## Adverse Reactions

**CNS**: Abnormal dreams or thinking, aggression, agitation, amnesia, apathy, asthenia, ataxia, attention disturbance, behavioral deterioration, catatonic reaction, cerebral pseudoatrophy, chills, cognitive decline, confusion, depression, dizziness, drowsiness, emotional upset, **encephalopathy**, euphoria, fever, gait abnormality, hallucinations, headache, hostility, hyperactivity, hyperesthesia, hypertonia, hypokinesia, **hypothermia**, increased reflexes, insomnia, irritability, lack of coordination, learning disorder, lethargy, **loss of seizure control**, malaise, nervousness, **paradoxical seizures**, paresthesia, parkinsonism, psychomotor hyperactivity, psychosis, sedation, speech disorder, somnolence, **suicidal ideation**, tardive dyskinesia, tremor, twitching, vertigo, weakness

**CV:** **Bradycardia**, chest pain, edema, hypertension, **hypotension**, orthostatic hypotension, palpitations, peripheral edema, tachycardia, vasodilation

**EENT:** Amblyopia, conjunctivitis, diplopia, dry eyes, ear or eye pain, glossitis, hearing loss, nystagmus, parotid gland swelling, pharyngitis, rhinitis, sinusitis, spots before eyes, stomatitis, taste perversion, tinnitus

**ENDO:** Breast enlargement, elevated testosterone level, galactorrhea, hyperandrogenism, hyperglycemia, inappropriate ADH secretion, parotid gland swelling

**GI:** Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, elevated liver enzymes, fecal incontinence, flatulence, gastroenteritis, **hepatotoxicity**, increased appetite, indigestion, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Aspermia, azoospermia, cystitis, decreased sperm count or spermatozoa motility, dysuria, enuresis, male infertility, menstrual irregularities, polycystic ovary disease, urinary incontinence, UTI, **vaginal hemorrhage**

**HEME:** **Agranulocytosis**, anemia, **aplastic anemia**, **bone marrow suppression**, eosinophilia, hematoma, **hypofibrinogenemia**, **leukopenia**, lymphocytosis, macrocytosis, **pancytopenia**, porphyria (acute, intermittent), **prolonged bleeding time**, **thrombocytopenia**

**MS:** Arthralgia, arthrosis, back pain, bone pain, decreased bone mineral density, dysarthria, fractures, leg cramps, myalgia, neck pain or rigidity, osteopenia, osteoporosis

**RESP:** Dyspnea, increased cough

**SKIN:** Alopecia, changes in hair color or texture, cutaneous vasculitis, diaphoresis, discoid lupus erythematosus, dry skin, ecchymosis, **erythema multiforme**, furunculosis, hair color or texture changes, hirsutism, maculopapular

rash, nail and nail bed disorders, petechiae, photosensitivity, pruritus, rash, seborrhea, **Stevens-Johnson syndrome, toxic epidermal necrolysis**

**Other: Anaphylaxis**, decreased carnitine concentration, developmental delay (children), **drug reaction with eosinophilia and systemic symptoms (DRESS)**, **hyperammonemia, hyponatremia**, injection-site pain, weight gain or loss

## Nursing Considerations

- Know that women of childbearing age should not be prescribed divalproex, valproate sodium, or valproic acid, unless other treatments have failed or are unacceptable because drug exposure very early on in pregnancy may cause decreased IQ and major congenital malformations in the fetus.
- Use caution when administering drug to children or patient with history of hepatic disease, patient receiving multiple anticonvulsants, patient with congenital metabolic disorders, severe seizure disorder accompanied by mental retardation, and organic brain disease, because they may be at increased risk for developing hepatotoxicity.
- Give oral divalproex or valproic acid with food to minimize GI irritation, if needed.
- Administer drug at least 2 hours before or 6 hours after cholestyramine.
- Don't mix syrup with carbonated beverages; result may be an unpleasant-tasting mixture and irritate mouth and throat.
- Don't break or let patient chew delayed-release or extended-release tablets.
- Know that, if needed, sprinkle contents of delayed-release sprinkle capsules on small amount of semisolid food just before administration. Instruct patient not to chew contents of delayed-release sprinkle capsules.
- For I.V. administration, dilute prescribed dose with at least 50 ml compatible diluent and infuse over 60 minutes.
- Know that patient should be switched from I.V. to P.O. form of valproic acid as soon as possible.

- Be aware that patient with hypoalbuminemia or another protein-binding deficiency is at increased risk for valproic acid toxicity.
- Watch for evidence of decreased hepatic function, including anorexia, facial edema, jaundice, lethargy, loss of seizure control, malaise, vomiting, and weakness, especially during the first 6 months of treatment.
- Monitor liver enzymes, as ordered. Notify prescriber immediately if hepatotoxicity is suspected and, if confirmed, expect drug to be discontinued immediately.
- Monitor platelet count, as ordered, for signs of thrombocytopenia, and notify prescriber if they appear.

**WARNING** Keep in mind hyperammonemia may occur even if liver function test results are normal. Monitor ammonia levels, as ordered. If patient develops unexplained lethargy, vomiting, or changes in mental status with an increase in ammonia level; if asymptomatic ammonia elevations are detected and persist; or if patient develops hypothermia even without hyperammonemia, expect to discontinue valproic acid.

- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Monitor patient's drug level, as ordered, especially early in therapy and if patient takes other drugs, because interactions can alter the blood level.
- Be aware drug may alter urine ketone test and thyroid function tests.

## **PATIENT TEACHING**

- Instruct patient to swallow capsules whole to prevent irritation to mouth and throat. However, delayed-release sprinkle capsules may be opened and contents mixed with food for easier swallowing. Instruct patient not to chew contents of delayed-release sprinkle capsules.
- Tell patient to notify prescriber immediately and withhold further doses of drug, unless advised otherwise by prescriber, if symptoms such as anorexia, facial edema, lethargy, malaise, weakness, and vomiting occur.

- Advise patient to avoid hazardous activities during therapy because drug may affect mental and motor performance.
- Urge patient to avoid alcohol during therapy.
- Advise patient to notify prescriber if tremor develops during therapy; it may be dose-related.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Instruct women of childbearing age to use effective contraception while taking drug and to notify prescriber if pregnancy is suspected or occurs, as valproate exposure in utero can cause adverse effects on the cognitive development of the unborn child. Encourage woman who becomes pregnant while taking valproic acid to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy.

## valsartan

### Diovan, Prexxartan

## Class and Category

*Pharmacologic class:* Angiotensin II receptor blocker (ARB)

*Therapeutic class:* Antihypertensive

*Pregnancy category:* D

## Indications and Dosages

- *To manage hypertension, alone or with other antihypertensives*

### ORAL SUSPENSION, TABLETS (DIOVAN)

**Adults.** *Initial:* 80 or 160 mg daily, increased as needed and prescribed. *Maximum:* 320 mg/day.

**Children ages 6 to 16.** 1.3 mg/kg (up to 40 mg total) once daily, increased as needed and prescribed. *Maximum:* 2.7 mg/kg (up to 160 mg) daily.

## **ORAL SOLUTION (PREXXARTAN)**

**Adults.** *Initial:* 40 mg or 80 mg twice daily, increased as needed and prescribed. *Maximum:* 320 mg/day.

**Children ages 6 to 16.** *Initial:* 0.65 mg/kg (up to maximum of 40 mg) twice daily, increased as needed and prescribed. *Maximum:* 1.35 mg/kg twice daily.

- *To treat New York Heart Association (NYHA) class II to IV heart failure*

## **ORAL SOLUTION (PREXXARTAN), ORAL SUSPENSION, TABLETS (DIOVAN)**

**Adults.** *Initial:* 40 mg twice daily, increased to 80 mg twice daily and then 160 mg twice daily, as needed. *Maximum:* 320 mg daily.

- *To reduce cardiovascular mortality in stable patients with left ventricular failure or dysfunction following an MI*

## **ORAL SOLUTION (PREXXARTAN), ORAL SUSPENSION, TABLETS (DIOVAN)**

**Adults.** *Initial:* 20 mg twice daily starting as early as 12 hr after MI, increased to 40 mg twice daily within 7 days, followed by subsequent adjustments to 160 mg twice daily as tolerated. *Maintenance:* 160 mg twice daily.

***DOSAGE ADJUSTMENT*** If patient develops symptomatic hypotension or renal dysfunction, dosage decreased.

Route	Onset	Peak	Duration
P.O.	2 hr	6 hr	24 hr

## Mechanism of Action

Blocks the hormone angiotensin II from binding to receptor sites in adrenal glands, vascular smooth muscle, and other tissues. This action inhibits aldosterone-secreting and vasoconstrictive effects of angiotensin II, thereby reducing blood pressure. It also reduces renal reabsorption of sodium, which helps to reduce fluid retention that occurs in heart failure.

## Contraindications

Concurrent aliskiren therapy in diabetic patients, hypersensitivity to valsartan or its components

## Interactions

### DRUGS

*ACE inhibitors, aliskiren, other angiotensin receptor blockers:* Increased risk of hypotension, hyperkalemia, and renal dysfunction

*antihypertensives, diuretics:* Additive hypotensive effect

*cyclosporine, rifampin, ritonavir:* Possibly increased blood valsartan level

*lithium:* Possibly increased serum lithium concentration and toxicity

*NSAIDs:* Increased risk of renal dysfunction, especially in the elderly and patients with or existing renal dysfunction or volume depletion

*potassium salts, potassium-sparing diuretics, potassium supplements:* Possibly hyperkalemia

## FOODS

*high potassium foods such as bananas or potatoes, potassium-containing salt substitutes: Possibly hyperkalemia*

## Adverse Reactions

**CNS:** Dizziness, fatigue, headache, insomnia, syncope, vertigo

**CV:** Edema, **hypotension**, orthostatic hypotension, vasculitis

**EENT:** Blurred vision, pharyngitis, rhinitis, sinusitis

**GI:** Abdominal pain, diarrhea, elevated liver enzymes, **hepatitis**, indigestion, nausea, vomiting

**GU:** **Acute renal failure**, increased blood creatinine level

**HEME:** **Thrombocytopenia**

**MS:** Arthralgia, back pain, **rhabdomyolysis**

**RESP:** Cough, upper respiratory tract infection

**SKIN:** Alopecia, bullous dermatitis, rash

**Other:** **Angioedema**, **hyperkalemia**, increased incidence of viral infection

## Nursing Considerations

- Know that valsartan shouldn't be given to patients who are taking a diuretic or have hypovolemia, because there is increased risk of severe hypotension from volume depletion. If severe hypotension occurs, place patient in a supine position, notify prescriber, and expect to give an intravenous infusion of normal saline.
- Be aware that Diovan tablets including the oral suspension form made from the tablets are not interchangeable with Prexxartan oral solution.
- Check patient's blood pressure often
- Be aware that maximal blood pressure reduction typically occurs after 4 weeks.

- during therapy.
- Monitor serum potassium level because drug may elevate potassium level by blocking aldosterone secretion.
- Obtain a serum creatinine level periodically, as ordered, because changes in renal function can occur during valsartan therapy. Know that patients who are at high risk for renal dysfunction are patients with chronic kidney disease, renal artery stenosis, severe congestive heart failure, or who are volume-depleted. Notify prescriber of an elevated serum creatinine level and changes in voiding patterns because renal dysfunction could lead to acute renal failure.

## **PATIENT TEACHING**

- Instruct patient to take valsartan exactly as prescribed at the same time each day to maintain therapeutic effect.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid using potassium-containing salt substitutes without consulting prescriber.
- Instruct female patient of childbearing age to use reliable birth control during therapy and to notify prescriber at once about known or suspected pregnancy, because valsartan will have to be discontinued.
- Urge patient to keep follow-up appointments to monitor progress.
- Tell patients to inform all prescribers of valsartan therapy and any other drug therapy they are taking, including drugs such as ibuprofen and naproxen.

**vancomycin hydrochloride**

**Firvanq, Vancocin**

## **Class and Category**

*Pharmacologic class:* Glycopeptide

*Therapeutic class:* Antibiotic

*Pregnancy category:* B (oral), C (parenteral)

## Indications and Dosages

- *To treat pseudomembranous colitis caused by Clostridium difficile*

### CAPSULES, ORAL SOLUTION

**Adults.** 125 mg every 6 hr for 7 to 10 days (capsules) or 10 days (oral solution). *Maximum:* 2 g daily.

**Children.** 40 mg/kg daily in three or four divided doses for 7 to 10 days. *Maximum:* 2 g daily.

- *To treat staphylococcal enterocolitis caused by Staphylococcus aureus*

### CAPSULES, ORAL SOLUTION

**Adults.** 500 mg to 2 g daily in three or four divided doses for 7 to 10 days.

**Children.** 40 mg/kg daily in three or four divided doses for 7 to 10 days. *Maximum:* 2 g daily.

- *To treat bacterial endocarditis caused by methicillin-resistant Staphylococcus aureus*

### I.V. INFUSION

**Adults.** 30 mg/kg daily infused at a rate of no more than 10 mg/min or over at least 1 hr, whichever is longer, in equally divided doses twice daily for 4 to 6 wk. *Maximum:* 2 g daily.

- *As adjunct to treat bacterial endocarditis caused by methicillin-resistant S. aureus in patients with*

*prosthetic heart valve*

## **I.V. INFUSION**

**Adults.** 30 mg/kg daily infused at a rate of no more than 10 mg/min or over at least 1 hr, whichever is longer, in equally divided doses twice daily to four times a day for 6 wk or longer in conjunction with rifampin and gentamicin. *Maximum:* 2 g daily.

- *To treat bacterial endocarditis caused by Streptococcus bovis or Streptococcus viridans*

## **I.V. INFUSION**

**Adults.** 30 mg/kg daily infused at a rate of no more than 10 mg/min or over at least 1 hr, whichever is longer, in equally divided doses twice daily for 4 wk. *Maximum:* 2 g daily.

- *As adjunct to treat bacterial endocarditis caused by enterococci*

## **I.V. INFUSION**

**Adults.** 30 mg/kg daily infused at a rate of no more than 10 mg/min or over at least 1 hr, whichever is longer, in equally divided doses twice daily for 4 to 6 wk in conjunction with gentamicin. *Maximum:* 2 g daily.

- *To treat bacterial septicemia, bone and joint infections, pneumonia, and skin and soft-tissue infections caused by staphylococcus, including methicillin-resistant strains, and life-threatening infections*

## **I.V. INFUSION**

**Adults and children age 12 and over.** 500 mg every 6 hr or 1 g every 12 hr, infused at a rate of no more than 10 mg/min or over at least 1 hr, whichever is longer.

*Maximum:* 4 g daily.

**Children ages 1 month to 12 years.** 10 mg/kg every 6 hr, infused over at least 60 min.

**Neonates ages 1 week to 1 month.** *Initial:* 15 mg/kg followed by 10 mg/kg every 8 hr, infused over at least 60 min.

**Neonates under age 1 week.** *Initial:* 15 mg/kg followed by 10 mg/kg every 12 hr, infused over at least 60 min.

## Mechanism of Action

Inhibits bacterial RNA and cell wall synthesis; alters permeability of bacterial membranes, causing cell wall lysis and cell death.

## Incompatibilities

Don't give I.V. vancomycin through same I.V. line as other drugs. Don't add to albumin-containing solutions, alkaline solutions, aminophylline, amobarbital sodium, aztreonam, cefepime, ceftazidime, chloramphenicol sodium succinate, chlorothiazide sodium, dexamethasone sodium phosphate, foscarnet sodium, heparin sodium, methicillin sodium, penicillin G, pentobarbital sodium, phenobarbital sodium, piperacillin sodium and tazobactam sodium, secobarbital sodium, and sodium bicarbonate. Vancomycin may precipitate with heavy metals.

## Contraindications

Hypersensitivity to corn or corn products when given with dextrose solutions, hypersensitivity to vancomycin or its

components

## Interactions

### DRUGS

*aminoglycosides (amikacin, gentamicin, tobramycin), amphotericin B, bacitracin (parenteral), bumetanide, capreomycin, carmustine, cidofovir, cisplatin, cyclosporine, ethacrynic acid, furosemide, paromomycin, pentamidine (parenteral), polymyxin B, salicylates (parenteral), streptozocin, viomycin*: Additive nephrotoxicity or ototoxicity

*antihistamines, buclizine, cyclizine, phenothiazines, thioxanthenes, trimethobenzamide*: Masked symptoms of ototoxicity

*cholestyramine, colestipol*: Decreased antibacterial activity of oral vancomycin

*dexamethasone*: Decreased penetration of vancomycin into cerebrospinal fluid

*nephrotoxic drugs*: Increased risk of nephrotoxicity

## Adverse Reactions

**CNS:** Chills, depression, dizziness, fatigue, fever, headache, insomnia, vertigo

**CV:** **Hypotension**, peripheral edema, vasculitis

**EENT:** Ototoxicity

**GI:** Abdominal pain, constipation, ***Clostridium difficile-associated diarrhea***, diarrhea, flatulence, nausea, vomiting

**GU:** **Acute kidney injury**, interstitial nephritis, **nephrotoxicity**, UTI

**HEME:** Anemia, eosinophilia, **neutropenia**, **thrombocytopenia**

**MS:** Back pain

**RESP:** Dyspnea, wheezing

**SKIN:** **Exfoliative dermatitis**; extravasation with pain, tenderness, thrombophlebitis, and tissue necrosis; pruritus; rash; **Stevens-Johnson syndrome**; **toxic epidermal necrolysis**; urticaria

**Other:** **Anaphylaxis**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, drug-induced fever, **hypokalemia**, injection-site inflammation, superinfection

## Nursing Considerations

- Be aware that vancomycin is not indicated for prophylaxis of endophthalmitis, nor should it be administered intracamerally or intravitreally, especially during or after cataract surgery, because it may cause hemorrhagic occlusive retinal vasculitis which may result in permanent vision loss.
- Reconstitute 500-mg vial of vancomycin for I.V. use by adding 10 ml of sterile water for injection; further dilute with at least 100 ml of compatible I.V. solution. For 1-g vial of dry, sterile powder, add 20 ml of sterile water for injection; further dilute with at least 200 ml of compatible I.V. solution.

**WARNING** Infuse over at least 1 hr/g of vancomycin. Rapid delivery may cause hypotension or transient “red man syndrome,” characterized by chills; fainting; fever; flushing of face, neck, torso and upper arms; hypotension; nausea; tachycardia; and vomiting.

- Expect to monitor blood vancomycin concentrations frequently. Higher trough concentrations of 15 to 20 mg/L are commonly targeted now, though they are associated with more nephrotoxicity than the lower trough concentrations previously used.
- Monitor serum vancomycin concentration in patients with colitis or renal impairment because significant increases in blood drug level have occurred in such patients taking multiple oral doses of vancomycin.
- Know that if patient has an inflammatory intestinal disorder, he should be assessed often for adverse reactions because vancomycin absorption may

be increased in these conditions.

- Check CBC results and BUN and serum creatinine levels during therapy, especially if patient has renal impairment or takes an aminoglycoside, because systemic vancomycin may cause acute kidney injury.
- Observe I.V. infusion site for evidence of extravasation, including necrosis, pain, tenderness, and thrombophlebitis. If extravasation occurs, discontinue infusion immediately and notify prescriber.
- Assess hearing during therapy. Transient or permanent ototoxicity may occur if patient receives an excessive amount of drug, has an underlying hearing loss, or receives concurrent aminoglycosides.
- Monitor patient closely for diarrhea when receiving intravenous form of vancomycin, because it may indicate pseudomembranous colitis caused by *C. difficile*, a risk with many antibiotics. If diarrhea occurs during therapy, notify prescriber and expect to withhold drug. If confirmed, treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Know that oral vancomycin is only used for gastrointestinal *C. difficile* and staphylococcal infections, as it is not absorbed. Patients cannot be converted from I.V. to oral vancomycin for other infections.

## PATIENT TEACHING

- Instruct patient to use a calibrated measuring device to measure accurate doses of oral solution.
- Advise patient to notify prescriber if no improvement occurs after a few days.
- Instruct patient to complete full course of vancomycin, as prescribed.
- Instruct patient to notify prescriber if she develops persistent or severe diarrhea.
- Instruct patient to keep follow-up appointments during and after treatment.

# sildenafil hydrochloride

## Levitra, Staxyn

---

## Class and Category

*Pharmacologic class:* Phosphodiesterase type 5 (PDE5) inhibitor

*Therapeutic class:* Anti-impotence agent

*Pregnancy category:* B

## Indications and Dosages

➤ *To treat erectile dysfunction*

### TABLETS (LEVITRA)

**Adults.** 10 mg taken 1 hr before sexual activity; increased to 20 mg or decreased to 5 mg, as needed. *Maximum:* 20 mg and once-daily limit regardless of dosage.

***DOSAGE ADJUSTMENT*** If patient takes ritonavir, vardenafil dosage shouldn't exceed 2.5 mg in 72 hr. If patient takes atazanavir, clarithromycin, indinavir, itraconazole 400 mg daily, ketoconazole 400 mg daily, saquinavir, or another potent CYP3A4 inhibitor, vardenafil dosage shouldn't exceed 2.5 mg in 24 hr. If patient takes erythromycin, itraconazole 200 mg daily, or ketoconazole 200 mg daily, vardenafil dosage shouldn't exceed 5 mg in 24 hr.

### ORALLY DISINTEGRATING TABLETS (STAXYN)

**Adults.** 10 mg taken 1 hr before sexual activity. *Maximum:* 10 mg within 24-hr period.

---

Route	Onset	Peak	Duration
P.O.	30 min	30 min-2 hr	4-5 hr

---

## Mechanism of Action

Enhances effect of nitric oxide (released in the penis by sexual stimulation) and inhibits phosphodiesterase type 5, which increases cGMP level, relaxes smooth muscle, increasing blood flow into the corpus cavernosum to produce an erection.

## Contraindications

Concurrent administration of alpha blockers or guanylate cyclase stimulators (riociguat), concurrent continuous or intermittent nitrate therapy, hypersensitivity to vardenafil or its components

## Interactions

### DRUGS

*alpha blockers, guanylate cyclase stimulators, nitrates:*

Profound hypotension

*atazanavir, clarithromycin, erythromycin, indinavir,*

*itraconazole, ketoconazole, ritonavir, saquinavir:* Increased vardenafil effects

*class IA (procainamide, quinidine) and class III*

*(amiodarone, sotalol) antiarrhythmics:* Possibly increased QT-interval prolongation

*indinavir, ritonavir:* Reduced blood levels of indinavir and ritonavir

### FOODS

*grapefruit juice:* Possibly increased vardenafil effect

## Adverse Reactions

**CNS:** Dizziness, headache, **seizures**, transient global amnesia

**CV:** **Hypotension, prolonged QT interval**

**EENT:** Decreased vision, hearing loss, loss of vision in one or both eyes, nasal congestion, nonarteritic anterior ischemic optic neuropathy (NAION), rhinitis, sinusitis, tinnitus

**GI:** Indigestion, nausea

**GU:** Priapism

**MS:** Back pain

**SKIN:** Flushing

**Other:** Flu-like symptoms

## Nursing Considerations

- Know that vardenafil shouldn't be used by men taking class IA (procainamide, quinidine) or class III (amiodarone, sotalol) antiarrhythmics or by men who have congenital prolonged QT interval. Drug may potentiate prolonged QT interval. It should also not be used in men who have hypotension (resting systolic blood pressure of less than 90 mm Hg), myocardial infarction (within last 6 months), presence of life-threatening arrhythmia, recent history of stroke, severe cardiac failure, uncontrolled hypertension (greater than 170/110 mm Hg), or unstable angina, because drug use could worsen these conditions.
- Use vardenafil cautiously in elderly men, men with penile abnormalities that may predispose them to priapism, or men with mild hepatic impairment (should not be used if patient has moderate to severe hepatic impairment), or renal dysfunction (although it should not be used if patient is on dialysis).
- Also use cautiously in patients with left ventricular outflow obstruction, such as aortic stenosis, and those with severely impaired autonomic control of blood pressure. These conditions increase sensitivity to vasodilators, such as vardenafil.
- Be aware that Levitra tablets are not interchangeable with Staxyn tablets.
- Monitor blood pressure and heart rate before and after giving drug, especially if patient takes an alpha blocker, because of increased risk of symptomatic hypotension.

- Monitor patient's vision, especially if he's over age 50; has coronary artery disease, diabetes, hyperlipidemia, or hypertension; or smokes, because vardenafil rarely leads to nonarteritic ischemic optic neuropathy and vision that is decreased, possibly permanently.
- Monitor patient's hearing. Sudden decrease or loss, possibly with dizziness and tinnitus, may occur with vardenafil use. Report such changes immediately, and expect drug to be discontinued.

## PATIENT TEACHING

- Alert patient that orally disintegrating tablets contain phenylalanine and should not be taken by patients with phenylketonuria. It also contains sorbitol and should not be taken if he has hereditary problems with fructose intolerance.
- Tell patient to take drug 1 hour before anticipated sexual activity for best results.
- Instruct patient to place a prescribed orally disintegrating tablet on his tongue immediately after removing it from the blister package and allow it to dissolve. He should not crush or split the tablet, and tablet should not be taken with any liquid.

**WARNING** Tell patient not to take vardenafil if he takes an organic nitrate, continuously or intermittently, or within 4 hours of taking an alpha blocker because profound hypotension and death could result.

- Caution patient not to take vardenafil more than once daily or to exceed 20 mg daily for oral tablet or 10 mg for orally disintegrating tablet. Tell him to call his prescriber or go to the emergency department immediately if he accidentally takes more vardenafil than prescribed.
- Tell patient to stop taking vardenafil and notify prescriber if he has a sudden hearing loss, sudden loss of vision in one or both eyes, or trouble remembering.
- Advise patient to seek sexual counseling to enhance drug's effects.
- Inform patient taking Staxyn that some form of sexual stimulation is needed for an erection to happen.
- Urge patient to notify prescriber at once if erection is painful or lasts longer than 4 hours, to avoid possible penile damage and permanent loss

of erectile function.

- Instruct patient to alert all prescribers of vardenafil use.

## varenicline

### Chantix

## Class and Category

*Pharmacologic class:* Nicotinic receptor partial agonist

*Therapeutic class:* Nicotinic blocker

*Pregnancy classification:* C

## Indications and Dosages

➤ *As adjunct to smoking cessation treatment*

### **TABLETS**

**Adults.** *Initial:* 0.5 mg daily for 3 days; then increased to 0.5 mg twice daily for 4 days, and then increased to 1 mg twice daily for a total of 12 wk of therapy. If effective, an additional 12 wk of therapy may be given.

***DOSAGE ADJUSTMENT*** If patient has severe renal impairment, maximum dosage is 0.5 mg twice daily. If patient is having hemodialysis for end-stage renal disease, maximum dosage is 0.5 mg daily.

## Mechanism of Action

Blocks nicotine from activating  $\alpha_4\beta_2$  receptors by binding to them. This inhibits nicotine stimulation of the central nervous mesolimbic dopamine system, which probably is the area that produces pleasure in and reinforcement of smoking.

## Contraindications

Hypersensitivity to varenicline or its components

## Interactions

### DRUGS

*nicotine (transdermal)*: Increased adverse reactions

### ACTIVITIES

*alcohol use*: Increased intoxicating effects of alcohol including aggressive behavior and sometimes amnesia of event

## Adverse Reactions

**CNS:** Abnormal dreams, aggression, agitation, anxiety, asthenia, attention difficulties, behavior changes, **CVA**, delusions, depression, dizziness, dysgeusia, fatigue, hallucinations, headache, **homicidal ideation**, hostility, insomnia, irritability, lethargy, loss of consciousness, malaise, mania, mental impairment, panic, paranoia, psychosis, restlessness, **seizures**, sensory disturbances, sleep disorder, sleepwalking, somnambulism, somnolence, **suicidal ideation**, thirst

**CV:** Angina, chest pain, edema, hypertension, **MI**, peripheral ischemia, **thrombosis**, **ventricular**

## extrasystole

**EENT:** Dry mouth, epistaxis, gingivitis, rhinorrhea

**ENDO:** Hot flashes, hyperglycemia

**GI:** Abdominal pain, **acute pancreatitis**, anorexia, constipation, diarrhea, dyspepsia, flatulence, gastroesophageal reflux disease, **GI hemorrhage**, increased appetite, liver enzyme abnormalities, nausea, splenomegaly, vomiting

**GU:** **Acute renal failure**, polyuria, urine retention

**HEME:** Leukocytosis, **thrombocytopenia**

**MS:** Arthralgia, back pain, muscle cramp, musculoskeletal pain, myalgia

**RESP:** **Asthma**, dyspnea, **pulmonary embolism**

**SKIN:** Diaphoresis, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** **Angioedema**, flu-like syndrome, **hyperkalemia**, **hypersensitivity reactions**, **hypokalemia**, lymphadenopathy

## Nursing Considerations

- Use cautiously in patients with renal disease because varenicline is substantially excreted by the kidneys.
- Review patient's medication history before starting varenicline because dosage adjustments may be needed for drugs such as insulin, theophylline, and warfarin.

**WARNING** Monitor patient for angioedema, difficult breathing, rash with mucosal lesions, or other signs of hypersensitivity. Report immediately, stop varenicline therapy, and provide supportive emergency care, as prescribed.

- If patient has nausea, the most common adverse reaction to varenicline, notify prescriber. Dosage reduction may help.

**WARNING** Know that serious neuropsychiatric adverse effects have occurred with varenicline use, even in patients with no prior psychiatric history. Aggressive or unusual behavior directed to self or others may be exhibited. Observe patient closely. If present, stop drug therapy immediately, notify prescriber, and provide safety measures to protect patient and others.

- Even with varenicline therapy, nicotine withdrawal symptoms and worsening of underlying psychiatric illness may occur with smoking cessation. If present, notify prescriber immediately, institute safety measures, and expect drug to be discontinued.
- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Monitor patient for seizures, especially within the first month of therapy, and in patients with a history of seizures or other factors that could lower their seizure threshold.

## **PATIENT TEACHING**

- Explain that using nicotine patches while taking varenicline won't increase its effectiveness and may increase adverse reactions such as dizziness, nausea, and vomiting.
- Instruct patient to set a date to quit smoking and then start taking varenicline 1 week before the quit date. Or, patient can begin therapy and then set a date to quit smoking between days 8 and 35 of treatment. Or, if patient is unable or unwilling to quit smoking right away, inform him that he can start taking varenicline and reduce smoking during the first 12 weeks of treatment as follows: during weeks 1-4, reduce number of cigarettes smoked daily by half; during weeks 5-8, reduce number of cigarettes smoked daily to reach one-quarter of the starting daily cigarettes smoked; and during weeks 9-12, keep reducing number of cigarettes smoked until zero is reached by week 12. Know that varenicline can be taken for an additional 12 weeks of therapy after smoking has stopped, if needed.
- Explain how to adjust dose when drug is used for smoking cessation. Tell patient to take drug after eating and with a full glass of water.

- Encourage patient to continue trying to stop smoking even if an early relapse occurs during varenicline therapy.

**WARNING** Tell patient to seek medical attention immediately if he develops difficulty breathing; mucosal lesions; rash or other skin reaction; swelling of his eyes, face, lips, mouth or neck; or any other signs of hypersensitivity during therapy.

- Inform patient that the most common adverse reactions to varenicline therapy are insomnia and nausea, usually transient. If they persist, patient should notify prescriber; dosage reduction may help.
- Caution patient to avoid hazardous activities until CNS effects of drug are known. Explain that near-miss traffic accidents and other accidental injuries have occurred in patients taking varenicline.
- Explain that strange, unusual, or vivid dreams may occur during therapy. Also inform patient that sleepwalking may occur that can lead to behavior that may be harmful to self, others, or property. If sleepwalking occurs, tell patient to stop taking drug and notify prescriber.

**WARNING** Tell patient and family or caregiver that nicotine withdrawal can occur even with varenicline use and that aggressive or unusual behavior can occur in patients with or without a history of mental illness. Tell them that if patient has an existing mental illness, varenicline therapy may worsen it. Inform them that sometimes these behaviors may become serious and can be directed to self or others and may be worsened by concomitant use of alcohol. Advise patient to avoid alcohol during varenicline therapy and urge family or caregiver to monitor patient closely for suicidal or homicidal tendencies, especially when therapy starts or dosage changes. Advise patient, family, or caregiver to notify prescriber about abnormal thinking or behavior and to stop taking drug immediately if this occurs.

- Instruct patient to seek emergency medical care if she experiences a seizure or new or worsening symptoms of cardiovascular disease such as calf pain when walking, chest pain, shortness of breath, or sudden onset of difficulty speaking, numbness, or weakness.
- Advise women who are breastfeeding while taking varenicline to monitor infant for excessive vomiting and seizures. If present, tell patient to stop taking varenicline and have infant seen by a pediatrician.

## vasopressin

(antidiuretic hormone [ADH])

**Pressyn (CAN)**

### Class and Category

*Pharmacologic class:* Posterior pituitary hormone

*Therapeutic class:* Antidiuretic hormone

*Pregnancy category:* C

### Indications and Dosages

- *To prevent or control symptoms of central diabetes insipidus caused by insufficient ADH*

#### SUBCUTANEOUS INJECTION

**Adults.** 5 to 10 units twice daily or three times a day, as needed.

#### I.M. INJECTION

**Adults.** 5 to 10 units twice daily or three times a day, as needed.

**Children.** 2.5 to 10 units three times a day or four times a day, as needed.

## **I.V. INFUSION**

**Adults and children.** 0.0005 units/kg/hr. Dosage doubled every 30 min, as needed. *Maximum:* 0.01 units/kg/hr.

➤ *To prevent or treat abdominal distention postoperatively*

## **I.M. INJECTION**

**Adults.** 5 units, increased to 10 units every 3 to 4 hr, as needed.

### **Mechanism of Action**

Vasopressin, a synthetic form of antidiuretic hormone, treats diabetes insipidus by decreasing urine output and raising urine osmolality. When vasopressin attaches to vasopressin 2 ( $V_2$ ) receptors on cell membranes in the nephron's collecting duct, it activates the enzyme adenyl cyclase to convert adenosine triphosphate (ATP) to cyclic adenosine monophosphate (cAMP). This action increases the collecting duct's permeability and enhances water reabsorption into the blood.

Route	Onset	Peak	Duration
I.M., SubQ	Unknown	Unknown	2-8 hr
I.V.	Unknown	Unknown	30-60 min

## Contraindications

Chronic nephritis with nitrogen retention, hypersensitivity to vasopressin or its components

## Interactions

### DRUGS

*carbamazepine, chlorpropamide, clofibrate, fludrocortisone, tricyclic antidepressants:* Increased

antidiuretic effect

*demeclocycline, lithium, norepinephrine*: Decreased antidiuretic effect

## Adverse Reactions

**CNS:** Dizziness, headache, light-headedness, tremor

**CV:** Angina, **MI**

**EENT:** Circumoral pallor

**ENDO:** **Water intoxication**

**GI:** Abdominal cramps, diarrhea, eructation, flatulence, intestinal hypermotility, nausea, vomiting

**SKIN:** Diaphoresis, pallor

**Other:** **Hypersensitivity reaction**

## Nursing Considerations

- Use vasopressin with extreme caution in patients with asthma, epilepsy, heart failure, or migraine headache because extracellular fluid may increase rapidly; in those with coronary artery disease because it may cause angina or MI; and in those with hypertension because it may increase blood pressure.
- Monitor fluid and electrolyte balance during therapy. Check intake and output at least every 8 hours, and watch for evidence of water intoxication and hyponatremia, including anuria, confusion, drowsiness, headache, listlessness, and weight gain.

## PATIENT TEACHING

- Teach patient how to administer vasopressin, if needed; stress the need to rotate injection sites.
- Urge patient to notify prescriber immediately if he has evidence of possible water intoxication, including anuria, confusion, drowsiness, headache, listlessness, and unexplained weight gain.
- Inform patient that abdominal cramps, nausea, and skin blanching will subside after a few minutes and can be minimized by drinking one or two

glasses of water.

## **venlafaxine hydrochloride**

**Effexor, Effexor XR, Venlafaxine E.R.**

## **desvenlafaxine**

**Khedeza**

## **desvenlafaxine fumarate**

**Desvenlafaxine ER**

## **desvenlafaxine succinate**

**Pristiq**

### **Class and Category**

*Pharmacologic class:* Selective serotonin and norepinephrine reuptake inhibitor (SSNRI)

*Therapeutic class:* Antidepressant

*Pregnancy category:* C

### **Indications and Dosages**

➤ *To treat and prevent relapse of major depression*

**E.R. CAPSULES (EFFEXOR XR)**

**Adults.** 75 mg daily with a meal at same time each day, morning or evening (for some patients, 37.5 mg daily for 4 to 7 days before increasing to 75 mg daily); then increased by 75 mg daily every 4 days, as prescribed. *Maximum:* 225 mg daily.

**DOSAGE ADJUSTMENT** Initial daily dose decreased by 25% to 50% for patients with mild to moderate renal impairment and by 50% for patients with hepatic impairment.

## **E.R. TABLETS (DESVENLAFAXINE ER, KHEDEZLA, PRISTIQ)**

**Adults.** 50 mg daily, with a meal, at the same time each day morning or evening

## **E.R. TABLETS (VENLAFAXINE ER)**

**Adults. Initial:** 75 mg daily as single dose (for some patients, 37.5 mg daily for 4 to 7 days before increasing to 75 mg daily); then increased by 75 mg daily every 4 days, as prescribed. *Maximum:* 225 mg daily.

**DOSAGE ADJUSTMENT** For patient with moderate to severe hepatic impairment or moderate renal impairment taking Pristiq, maximum dosage is 50 mg daily. For patient with severe renal impairment, 50 mg every other day or, with Pristiq brand, dosage reduced to 25 mg daily or 50 mg every other day.

## **TABLETS (EFFEXOR)**

**Adults.** 75 mg daily in divided doses twice daily or three times a day, increased by 75 mg daily every 4 days, as needed. *Maximum:* 375 mg daily (225 mg/day for outpatients).

**DOSAGE ADJUSTMENT** For patients with mild to moderate hepatic impairment, dosage reduced by 50% or more. For

patients with mild to moderate renal impairment, dosage reduced by 25% or, if patient is undergoing hemodialysis, dosage reduced by 50%.

➤ *To treat generalized anxiety disorder*

## **E.R. CAPSULES (EFFEXOR XR)**

**Adults.** 75 mg daily with a meal at same time each day, morning or evening (for some patients, 37.5 mg daily for 4 to 7 days before increasing to 75 mg daily); then increased by 75 mg daily every 4 days, as needed. *Maximum:* 225 mg daily.

➤ *To treat social anxiety disorder*

## **E.R. CAPSULES (EFFEXOR XR)**

**Adults.** 75 mg daily.

## **E.R. TABLETS (VENLAFAXINE ER)**

**Adults.** 75 mg daily as a single dose.

➤ *To treat panic disorder*

## **E.R. CAPSULES (EFFEXOR XR)**

**Adults.** *Initial:* 37.5 mg daily for 7 days, increased to 75 mg daily, as needed; then increased by 75 mg daily every 4 days, as needed. *Maximum:* 225 mg daily.

***DOSAGE ADJUSTMENT*** Initial daily dose of E.R. capsules decreased by 25% to 50% for patients with mild to moderate renal impairment and by 50% for patients with hepatic impairment.

Route	Onset	Peak	Duration
P.O.	2 wk	Unknown	Unknown

# Mechanism of Action

Inhibits neuronal reuptake of norepinephrine and serotonin, along with its active metabolite, *O*-desmethylvenlafaxine. These actions raise norepinephrine and serotonin levels at nerve synapses, elevating mood and reducing depression.

# Contraindications

Hypersensitivity to desvenlafaxine, venlafaxine, or their components; use of an MAO inhibitor within 14 days, including intravenous methylene blue and linezolid

# Interactions

## DRUGS

*aspirin, NSAIDs, other serotonin-norepinephrine reuptake inhibitors, selective serotonin reuptake inhibitors, warfarin and other anticoagulants:* Increased risk of bleeding

*cimetidine:* Decreased clearance and increased levels of desvenlafaxine and venlafaxine

*clozapine:* Possibly increased blood clozapine level and serious adverse reactions, including seizures

*CYP3A4 inhibitors, ketoconazole:* Increased plasma venlafaxine level and risk of adverse reactions

*MAO inhibitors:* Increased risk of hypertension; hyperthermia; mental status changes, including coma and delirium; muscle rigidity; and severe myoclonus

*metoprolol:* Increased plasma metoprolol level, but decreased effectiveness in lowering blood pressure

*serotonergic drugs such as amitriptyline, amphetamines, buspirone, clomipramine, desipramine, doxepin, fentanyl, haloperidol, imipramine, linezolid, lithium, nortriptyline,*

*protriptyline, St. John's wort, tramadol, trazodone, triptans:*  
Possibly serotonin syndrome  
*warfarin:* Possibly increased PT, partial thromboplastin  
time, and INR

## ACTIVITIES

*alcohol use:* Increased CNS effects

## Adverse Reactions

**CNS:** Abnormal dreams, agitation, amnesia, anxiety, asthenia, attention disturbance, bruxism, **cerebral ischemia**, chills, confusion, delirium, delusions, depersonalization, depression, dizziness, dream disturbances, drowsiness, dyskinesia, extrapyramidal disorder, fatigue, fever, hallucinations, headache, hypesthesia, hypomania, impaired balance and coordination, insomnia, irritability, mania, migraine, mood changes, nervousness, **neuroleptic malignant syndrome**, paresthesia, **seizures**, **serotonin syndrome**, somnolence, **suicidal ideation**, syncope, tardive dyskinesia, tremor, vertigo

**CV:** **Arrhythmias**, **AV block**, chest pain, **congestive heart failure**, elevated cholesterol and triglyceride levels, edema, **extrasystoles**, hypertension, **hypotension**, **MI**, palpitations, **prolonged QT interval**, sinus tachycardia, **Takotsubo cardiomyopathy**, thrombophlebitis, **torsades de pointes**, vasodilation, **ventricular fibrillation or tachycardia**, worsening of peripheral vascular disease

**EENT:** Abnormal vision, accommodation abnormality, angle-closure glaucoma, blurred vision, dry mouth, mucous membrane bleeding, mydriasis, pharyngitis, rhinitis, taste alteration, tinnitus

**ENDO:** Elevated blood prolactin levels, hot flashes, hyperglycemia, syndrome of inappropriate ADH secretion

**GI:** Abdominal pain, anorexia, colitis, constipation, diarrhea, elevated liver enzymes, flatulence, **GI hemorrhage, hepatitis**, indigestion, nausea, **pancreatitis**, vomiting

**GU:** Anorgasmia (women), decreased libido, ejaculation disorder, impotence, urinary incontinence or urgency, urine hesitancy or retention

**HEME:** **Abnormal bleeding, agranulocytosis**, anemia, **aplastic anemia**, leukocytosis, **leukopenia, neutropenia, pancytopenia, prolonged bleeding time, thrombocytopenia**

**MS:** Neck pain, musculoskeletal stiffness, **rhabdomyolysis**

**RESP:** Cough, eosinophilic pneumonia, increased dyspnea, **interstitial lung disease**

**SKIN:** Diaphoresis, ecchymosis, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**

**Other:** **Angioedema, hypersensitivity reactions, hyponatremia**, lymphadenopathy, weight gain or loss

## Nursing Considerations

- Be aware that desvenlafaxine and venlafaxine should not be given to patients with bradycardia, congenital long QT syndrome, hypokalemia or hypomagnesemia, recent acute myocardial infarction, or uncompensated heart failure because of increased risk of prolonged QT interval and torsades de pointes. It should also not be given to patients who are taking other drugs that prolong the QT interval. Expect hypokalemia and hypomagnesemia to be corrected before drug therapy is begun.
- Use cautiously in patients with a history of mania because desvenlafaxine and venlafaxine therapy may worsen condition. Also use cautiously in patients with a history of seizures, and expect to discontinue drug, as ordered, if seizures occur.

- Use cautiously in patients who have medical conditions that might be made worse by an increased heart rate, as in heart failure, hyperthyroidism, or recent MI.

**WARNING** Be aware that serotonin syndrome in its most severe form may resemble neuroleptic malignant syndrome, which includes autonomic instability with possibly rapid changes in vital signs, hyperthermia, mental status changes, and muscle rigidity. Notify prescriber, withhold drug immediately, and provide supportive care. Expect drug to be discontinued.

- Monitor blood pressure often during therapy because it may cause dose-related sustained increase in supine diastolic pressure. Expect to reduce or stop drug, as prescribed, if increase develops.
- Assess patient's electrolyte balance, as ordered, because drug can cause hyponatremia, especially in elderly patients and in patients who take diuretics or are volume-depleted. If patient has evidence of hyponatremia (confusion, headache, trouble concentrating, unsteadiness, weakness), notify prescriber. If imbalance is confirmed, expect to stop drug and give appropriate care.
- Watch patient for suicidal tendencies, especially when therapy starts and dosage changes.
- Be aware that false-positive urine immunoassay screening tests for amphetamine and phencyclidine (PCP) have been found in patients taking desvenlafaxine or venlafaxine. Expect different testing to be done to distinguish drug from PCP and amphetamine.

**WARNING** Know that drug shouldn't be stopped abruptly, because doing so may cause multiple adverse effects, including asthenia, dizziness, flu-like symptoms, headache, insomnia, and nervousness.

- Monitor patient closely for abnormal bleeding that may range from ecchymosis to life-threatening hemorrhage. Know that concomitant use of desvenlafaxine and venlafaxine and drugs known to affect bleeding or coagulation increases the risk of bleeding.

## **PATIENT TEACHING**

- Instruct patient not to chew or crush E.R. capsules or tablets. If she has trouble swallowing capsules, tell her to open capsule, sprinkle contents on a spoonful of applesauce, and swallow immediately without chewing, followed by a glass of water.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute closure glaucoma. Encourage patient to have an eye exam before starting therapy to see if he is at risk.
- Advise patient to avoid alcohol during desvenlafaxine or venlafaxine therapy.
- Advise patient not to stop taking desvenlafaxine or venlafaxine abruptly.
- Caution patient to notify prescriber if she becomes pregnant during therapy because she'll need a different antidepressant. Taking desvenlafaxine or venlafaxine during third trimester of pregnancy increases risk of complications in the newborn.
- Advise patient to tell prescriber about all other prescribed drugs or OTC products she takes because of risk of interactions.
- Urge caregivers to monitor patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Alert patient that fertility impairment may occur while taking desvenlafaxine or venlafaxine. If this is a concern for the patient, instruct her to discuss with prescriber.
- Caution patient to avoid aspirin and NSAIDs, if possible, while taking desvenlafaxine or venlafaxine.
- Inform patient that urine screening tests for amphetamine and phencyclidine (PCP) may produce a false-positive for several days following discontinuation of desvenlafaxine or venlafaxine therapy, but that other tests may be done to distinguish drug from amphetamine and PCP.

**WARNING** Tell patient to report immediately sudden-onset, persistent, severe, or unusual symptoms.

- Tell patient to inform all prescribers of desvenlafaxine or venlafaxine therapy and not to take any over-the-counter medications, including herbal preparations, without prescriber knowledge.

# verapamil

**Apo-Verap (CAN), Calan, Novo-Veramil (CAN), Nu-Verap (CAN)**

## verapamil hydrochloride

**Calan SR, Covera-HS, Verelan, Verelan PM**

### Class and Category

*Pharmacologic class:* Calcium channel blocker

*Therapeutic class:* Antianginal, antiarrhythmic, antihypertensive

*Pregnancy category:* C

### Indications and Dosages

➤ *To treat chronic angina pectoris*

#### **TABLETS (VERAPAMIL)**

**Adults and adolescents age 15 and over.** *Initial:* 80 to 120 mg three times a day, increased every day or wk, as needed. *Maximum:* 480 mg daily in divided doses.

#### **TABLETS (COVERA-HS)**

**Adults.** *Initial:* 180 mg at bedtime. If response inadequate, dosage may be titrated to 180 mg at bedtime, then to 360

mg at bedtime, and 480 mg at bedtime, as needed.  
*Maximum:* 480 mg daily at bedtime.

➤ *To manage hypertension*

## **E.R. CAPSULES (VERAPAMIL HYDROCHLORIDE)**

**Adults and adolescents.** *Initial:* 240 mg daily, increased every day or wk, as needed. *Maximum:* 480 mg daily.

## **E.R. TABLETS (VERAPAMIL HYDROCHLORIDE)**

**Adults and adolescents.** *Initial:* 180 mg daily, increased every day or wk, as needed, according to following schedule: 240 mg daily in the morning; 180 mg every 12 hr or 240 mg in the morning and 120 mg in the evening; then 240 mg every 12 hr. *Maximum:* 480 mg daily in divided doses.

## **TABLETS (VERAPAMIL)**

**Adults and adolescents age 15 and over.** *Initial:* 80 to 120 mg three times a day, increased every day or wk, as needed. *Maximum:* 480 mg daily in divided doses.

## **E.R. CAPSULES (VERELAN PM)**

**Adults.** *Initial:* 200 mg at bedtime, increased to 300 mg at bedtime, then to 400 mg at bedtime, if needed.

## **E.R. TABLETS (COVERA-HS)**

**Adults.** *Initial:* 180 mg at bedtime. If response inadequate, dosage may be titrated to 180 mg at bedtime, then to 360 mg at bedtime, and 480 mg at bedtime, as needed.  
*Maximum:* 480 mg daily at bedtime.

➤ *To prevent or treat supraventricular tachycardia*

## TABLETS (VERAPAMIL)

**Adults and adolescents age 15 and over.** *Initial:* 80 to 120 mg three times a day, increased every day or wk, as needed. *Maximum:* 480 mg daily in divided doses.

**DOSAGE ADJUSTMENT** Initial P.O. dosage, possibly reduced for elderly and low-weight patients and those with impaired hepatic or left ventricular function. Dosage may need to be reduced in patients with decreased neuromuscular transmission.

## I.V. INJECTION (VERAPAMIL HYDROCHLORIDE)

**Adults and adolescents age 15 and over.** *Initial:* 5 to 10 mg slowly over 2 min; then 10 mg, as needed, if response isn't adequate after 30 min.

**Children ages 1 to 15.** *Initial:* 100 to 300 mcg/kg slowly over 2 min, up to maximum of 5 mg; then dosage repeated as needed, if response isn't adequate after 30 min.

**Infants up to age 1.** *Initial:* 100 to 200 mcg/kg slowly over 2 min; then dosage repeated, as needed, if response isn't adequate after 30 min.

**DOSAGE ADJUSTMENT** I.V. drug administered over 3 minutes in elderly patients.

Route	Onset	Peak	Duration
P.O.	1-2 hr	30-90 min	6-8 hr
P.O. (E.R.)	1-2 hr	30-90 min	Unknown
I.V.	1-5 min	3-5 min	10 min-6 hr

## Mechanism of Action

Inhibits calcium movement into coronary and vascular smooth-muscle cells by blocking slow calcium channels in

cell membranes. The resulting decrease in intracellular calcium level has the following effects:

- inhibits smooth-muscle cell contractions
- decreases myocardial oxygen demand by relaxing coronary and vascular smooth muscle, reducing peripheral vascular resistance, and decreasing systolic and diastolic pressures
- slows AV conduction time and prolongs AV nodal refractoriness
- interrupts reentry circuit in AV nodal reentrant tachycardias.

## Incompatibilities

Don't mix I.V. verapamil with albumin, amphotericin B injection, hydralazine hydrochloride injection, nafcillin, or sulfamethoxazole and trimethoprim injection. Solutions with pH above 6.0 cause precipitation.

## Contraindications

Cardiogenic shock, concomitant use of beta blockers (with I.V. verapamil) or ivabradine, hypersensitivity to verapamil or its components, hypotension, severe heart failure unless secondary to supraventricular tachycardia that responds to verapamil, severe left ventricular dysfunction, sick sinus syndrome or second- or third-degree heart block unless artificial pacemaker is in place, ventricular tachycardia (with I.V. verapamil)

## Interactions

### DRUGS

*alpha blockers, antihypertensives, general anesthetics (hydrocarbon), prazosin:* Hypotensive effects  
*aspirin:* Increased bleeding time

*beta blockers*: Increased risk of heart failure, hypotension, and severe bradycardia

*calcium supplements*: Decreased response to verapamil  
*carbamazepine, cyclosporine, theophylline, valproate*:

Increased risk of toxicity from these drugs

*cimetidine*: Decreased metabolism and increased blood level of verapamil

*clonidine*: Increased risk of severe sinus bradycardia

*cyclophosphamide, oncovin, procarbazine, prednisone (COPP) regimen; vindesine, adriamycin, cisplatin (VAC)*

*regimen*: Decreased verapamil absorption

*dantrolene*: Increased risk of hyperkalemia and myocardial depression

*digoxin*: Increased blood digoxin level and risk of digitalis toxicity

*disopyramide, flecainide*: Additive negative inotropic effects

*doxorubicin*: Increased plasma doxorubicin level

*erythromycin, ritonavir*: Increased blood verapamil level

*HMG-CoA reductase inhibitors such as atorvastatin,*

*lovastatin, and simvastatin*: Increased risk of myopathy and rhabdomyolysis

*ivabradine*: Increased exposure to ivabradine with possible exacerbation of bradycardia and conduction disturbances

*lithium*: Increased risk of neurotoxicity

*neuromuscular blockers*: Prolonged recovery from neuromuscular blockade

*NSAIDs, sympathomimetics*: Decreased antihypertensive effect of verapamil

*paclitaxel*: Decreased paclitaxel clearance

*phenobarbital*: Increased verapamil clearance

*procainamide*: Increased QT interval, additive negative inotropic effects

*protein-bound drugs (hydantoins, salicylates, sulfonamides, sulfonylureas, and warfarin and other oral anticoagulants)*:

Altered blood levels of these drugs

*quinidine*: Increased risk of quinidine toxicity, increased QT interval, additive negative inotropic effects

*rifampin*: Decreased bioavailability of oral verapamil

*telithromycin*: Increased risk of bradyarrhythmias, hypotension, and lactic acidosis

## **FOODS**

*grapefruit juice*: Increased verapamil level

## **ACTIVITIES**

*alcohol use*: Increased blood alcohol level and prolonged CNS effects

## **Adverse Reactions**

**CNS**: Asthenia, confusion, **CVA**, disequilibrium, dizziness, equilibrium disorders, extrapyramidal reactions, fatigue, headache, insomnia, paresthesia, psychosis, shakiness, somnolence, syncope

**CV**: **Abnormal ECG**, angina, **AV conduction disorders**, **bradycardia**, claudication, **heart failure**, hypertension, **hypotension**, **MI**, palpitations, peripheral edema, tachycardia, vasculitis

**EENT**: Blurred vision, dry mouth, tinnitus

**ENDO**: Gynecomastia, hyperprolactinemia

**GI**: Constipation, diarrhea, elevated liver enzymes, GI distress, nausea

**GU**: Galactorrhea, impotence, increased urination, menstrual irregularities

**MS**: Arthralgia, muscle spasms

**RESP**: Dyspnea, **pulmonary edema**

**SKIN**: Alopecia, diaphoresis, ecchymosis, **erythema multiforme**, exanthema, flushing, hyperkeratosis, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** Allergy aggravated

## Nursing Considerations

- Administer I.V. verapamil with compatible solutions, including D<sub>5</sub>W, normal saline solution, or Ringer's injection.
- Maintain continuous ECG monitoring and keep emergency resuscitative equipment and drugs readily available during I.V. therapy.
- Assess patient with hypertrophic cardiomyopathy or idiopathic hypertrophic subaortic stenosis for early development of hypotension and pulmonary edema, because second-degree AV block and sinus arrest can result.
- Assess for bradycardia and hypotension, and notify prescriber if blood pressure or heart rate declines significantly.
- Know that disopyramide or flecainide shouldn't be given within 48 hours before or 24 hours after verapamil because additive negative inotropic effects can result.
- Institute measures to prevent constipation, including a high-fiber diet and a stool softener, as prescribed.

## PATIENT TEACHING

- Instruct patient not to chew or crush verapamil E.R. capsules or tablets. Inform her that she may break E.R. tablets in half if necessary to aid swallowing.
  - Direct patient to check her pulse before taking verapamil and to notify prescriber if it's below 50 beats/minute or as instructed by prescriber.
  - Caution patient about possible dizziness and the need to avoid potentially hazardous activities until drug's CNS effects are known.
  - Inform patient that adverse skin reactions may subside with continued verapamil use. Advise her to notify prescriber if rash persists.
  - Encourage patient to increase dietary fiber intake to help prevent constipation. Advise her to notify prescriber if problem becomes persistent or severe.
-

# vigabatrin

**Sabril**

## Class and Category

*Pharmacologic class:* Gamma aminobutyric acid (GABA) transaminase inhibitor

*Therapeutic class:* Anticonvulsant

*Pregnancy category:* C

## Indications and Dosages

- *As adjunct therapy for refractory complex partial seizures in patients with inadequate response to several alternative treatments and for whom potential benefits outweigh the risk of vision loss*

### TABLETS

**Adults, adolescents 17 years and over, and children age 10 to 16 weighing more than 60 kg (132 lb).**

*Initial:* 500 mg twice daily, increased weekly in 500 mg increments, as needed. *Maximum:* 1.5 g twice daily.

**Children age 10 to 16 years of age weighing 60 kg (132 lb) or less.**

*Initial:* 250 mg twice daily, increased weekly in 500 mg/day increments, as needed. *Maximum:* 1 g twice daily.

***DOSAGE ADJUSTMENT*** For patient with mild renal impairment (creatinine clearance 51 to 80 ml/min), reduce dose by 25%. For patients with moderate renal impairment (creatinine clearance 31 to 50 ml/min), reduce dose by

50%. For patients with severe renal impairment (creatinine clearance 11 to 30 ml/min), reduce dose by 75%.

- *As monotherapy for pediatric patients with infantile spasms for whom potential benefits outweigh risk of vision loss*

## ORAL SOLUTION

**Children age 1 month to 2 years.** *Initial:* 50 mg/kg/day in two divided doses, increased every 3 days by 25 to 50 mg/kg/day, as needed. *Maximum:* 150 mg/kg/day in two divided doses.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

## Mechanism of Action

Inhibits the action of gamma aminobutyric acid transaminase (GABA-T), the enzyme responsible for metabolism of the inhibitory neurotransmitter GABA. This increases GABA level in the CNS, which may play a role in suppression of seizure activity.

## Contraindications

Hypersensitivity to vigabatrin and its components

## Interactions

### DRUGS

*phenytoin:* Decreased serum phenytoin level

# Adverse Reactions

**CNS:** Abnormal behavior or dreams, abnormal magnetic resonance imaging (MRI), acute psychosis, anxiety, apathy, asthenia, attention disturbance, confusion, coordination abnormality, delirium, depression, dizziness, dystonia, **encephalopathy**, expressive language disorder, fatigue, fever, gait disturbance, headache, hyperreflexia, hypertonia, hypoesthesia, hyporeflexia, hypomania, hypotonia, insomnia, irritability, lethargy, malaise, **malignant hyperthermia**, memory loss, myoclonus, nervousness, paresthesia, peripheral neuropathy, postictal state, **seizures**, sensory disturbance, somnolence, **status epilepticus**, **suicidal ideation**, thirst, tremor, vertigo

**CV:** Chest pain, edema, peripheral edema

**EENT:** Asthenopia, blurred vision, deafness, diplopia, eye pain, **laryngeal edema**, nasopharyngitis, nystagmus, optic neuritis, pharyngolaryngeal pain, **stridor**, tinnitus, toothache, tunnel vision, vision loss (permanent and severe), visual field defect

**ENDO:** Delayed puberty

**GI:** Abdominal or stomach pain, cholestasis, constipation, decreased liver enzymes, diarrhea, distention, dyspepsia, esophagitis, **GI hemorrhage**, nausea, vomiting

**GU:** Dysmenorrhea, erectile dysfunction, UTI

**HEME:** Anemia

**MS:** Arthralgia; back or limb pain; dysarthria; muscle spasticity, spasms or twitching

**RESP:** Bronchitis, cough, **pulmonary edema**, **respiratory failure**, upper respiratory infection

**SKIN:** Alopecia, maculopapular rash, pruritus, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** **Angioedema**, birth defects, developmental delay, flu-like symptoms, **multiorgan failure**, weight gain

# Nursing Considerations

- Be aware that vigabatrin therapy is only available under a restricted distribution program called the Sabril REMS program (1-888-457-4273).

**WARNING** Monitor patient's vision, and make sure patient has been examined by an ophthalmic professional in which visual fields and retinal examination has been performed no later than 4 weeks after vigabatrin therapy has begun and then every 3 months throughout therapy and 3 to 6 months after therapy has been discontinued, because drug can cause progressive and permanent bilateral concentric visual field constriction and severely reduce visual acuity. Be aware that while risk increases with total dose and duration of therapy, all patients are at risk for visual abnormalities even after drug has been stopped. Because of the risk of permanent and possibly severe vision loss, drug can be prescribed and obtained only through the REMS distribution program. Report any visual abnormalities immediately, and expect drug to be discontinued.

- Know that abnormal MRI results have been noted in some infants receiving vigabatrin.
- Monitor patient for suicidal ideation throughout therapy but especially when therapy starts or dosage changes.
- When discontinuing vigabatrin therapy, expect to do so gradually by decreasing daily dose by 1 g each week until drug is discontinued, as ordered.
- When discontinuing vigabatrin therapy in children, expect to do so gradually by decreasing dose by 25 to 50 mg/kg/day every 3 to 4 days.
- Monitor patient for evidence of peripheral neuropathy, such as numbness or tingling in feet or toes, progressive loss of reflexes, starting at the ankles, or reduced distal lower limb position sense or vibration. Alert prescriber if abnormalities are present.
- Assess patient routinely for edema, including peripheral edema.

## PATIENT TEACHING

- Explain the risk of possibly permanent vision loss that may occur as blurred vision or tunnel vision before patient starts vigabatrin. Stress the importance of having vision checked every 3 months throughout therapy and 3 to 6 months after drug is discontinued even if patient is an infant. However, inform patient that vision testing may be insensitive and may not detect vision loss before it is severe and has become permanent.
- Warn patient not to stop taking vigabatrin abruptly; she will need to be weaned off drug gradually over several weeks.
- Instruct parents how to mix the oral solution by emptying the entire contents of each 500-mg packet needed into a clean cup and dissolved in 10 ml of cold or room-temperature water per packet. Show parents how to administer the resulting solution using the 10-ml oral syringe supplied with the medication. Remind them that the concentration of the final solution is 50 mg/ml. Stress importance of checking dosage before administering.
- Advise female patient of childbearing age to use effective contraception if sexually active and to report suspected or confirmed pregnancy immediately.
- Advise patient or caregiver to notify prescriber if patient has unusual behaviors or feelings, especially if related to suicidal ideation and particularly at the beginning of therapy and during dosage adjustments.
- Caution patient not to perform hazardous activities such as operating equipment until CNS effects of the drug are known.
- Alert patient to monitor his weight because drug may cause weight gain.

**vilazodone hydrochloride**

**Viibryd**

## Class and Category

*Pharmacologic class:* Selective serotonin reuptake inhibitor (SSRI)

*Therapeutic class:* Antidepressant

*Pregnancy category:* C

## Indications and Dosages

➤ *To treat major depressive disorder*

### **TABLETS**

**Adults.** *Initial:* 10 mg once daily for 7 days, followed by 20 mg once daily for 7 days, then increased to 40 mg once daily as needed.

***DOSAGE ADJUSTMENT*** For patients taking a strong inhibitor of CYP3A4 such as ketoconazole, dosage should not exceed 20 mg daily. For patients taking a strong CYP3A4 inducer such as carbamazepine for more than 14 days, dosage may be increased up to twofold but not exceeding 80 mg daily.

## Mechanism of Action

Exerts antidepressant effects by potentiating serotonin activity in CNS and inhibiting serotonin reuptake at the presynaptic neuronal membrane. Blocked serotonin reuptake increases levels and prolongs activity of serotonin at synaptic receptor sites.

## Contraindications

Hypersensitivity to vilazodone or its components, use within 14 days of MAO inhibitor therapy

## Interactions

## DRUGS

*amphetamines, buspirone, fentanyl, lithium, MAO inhibitors, serotonin norepinephrine reuptake inhibitors, serotonin reuptake inhibitors, St. John's wort, tramadol, tricyclic antidepressants, triptans, tryptophan:* Increased risk of life-threatening adverse effects such as serotonin syndrome

*aspirin, NSAIDs, warfarin, and other anticoagulants:* Increased risk of bleeding

*CYP2C8 substrate, highly protein bound drugs:* Possibly increased blood concentration of the CYP2C8 substrate or highly protein bound drug

*CYP3A4 inhibitors such as erythromycin, ketoconazole:* Increased blood vilazodone levels with increased risk of adverse effects

## Adverse Reactions

**CNS:** Abnormal dreams, dizziness, fatigue, feeling jittery, hallucinations, insomnia, irritability, mania, migraine, **neuroleptic malignant syndrome-like reactions**, panic attack, paresthesia, restlessness, **seizures**, **serotonin syndrome**, sleep paralysis, **suicidal ideation**, tremor

**CV:** Palpitations, **prolonged QT interval**, **torsades de pointes**, **ventricular extrasystoles**

**EENT:** Angle-closure glaucoma, blurred vision, cataracts, dry eyes or mouth

**GI:** **Acute pancreatitis**, anorexia, diarrhea, dyspepsia, flatulence, gastroenteritis, **GI bleeding**, increased appetite, nausea, vomiting

**GU:** Decreased libido, delayed ejaculation, erectile dysfunction, pollakiuria

**HEME:** **Bleeding events**

**MS:** Arthralgia

**SKIN:** Diaphoresis, drug eruption, night sweats, rash, urticaria

## Nursing Considerations

- Be aware that vilazodone should not be given to patients with bradycardia, congenital long QT syndrome, hypokalemia or hypomagnesemia, recent acute myocardial infarction, or uncompensated heart failure because of increased risk of prolonged QT interval and torsades de pointes. It should also not be given to patients who are taking other drugs that prolong the QT interval. Expect hypokalemia and hypomagnesemia to be corrected before vilazodone therapy is begun.
- Use vilazodone cautiously in a patient with a seizure disorder because drug effect has not been studied in patients with seizures.
- Expect to taper vilazodone therapy gradually when drug is no longer required; abrupt discontinuation can precipitate withdrawal symptoms.

**WARNING** Monitor patient closely for serotonin syndrome exhibited by agitation, coma, diarrhea, hallucinations, hyperreflexia, hyperthermia, incoordination, labile blood pressure, nausea, tachycardia, or vomiting. Notify prescriber immediately because serotonin syndrome may be life-threatening; provide supportive care.

**WARNING** Be aware that serotonin syndrome in its most severe form may resemble neuroleptic malignant syndrome, which includes autonomic instability with possibly rapid changes in mental status and vital signs, hyperthermia, and muscle rigidity. Stop drug immediately, and provide supportive care.

- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Watch for mania, which may result from any antidepressant in a susceptible patient.

- Monitor patient closely for evidence of GI bleeding, especially if patient also takes a drug known to cause GI bleeding, such as aspirin, an NSAID, or warfarin.
- Monitor patient's serum sodium level, as ordered, especially in the elderly and patients with volume depletion, because selective serotonin reuptake inhibitors, the class of drugs vilazodone belongs to, have caused hyponatremia. If patient develops a confusion, difficulty concentrating, headache, memory impairment, unsteadiness, and weakness, and sodium level has decreased, notify prescriber and expect drug to be discontinued. Be prepared to provide supportive care.

## **PATIENT TEACHING**

- Instruct patient to take vilazodone with food because drug may not be as effective if taken on an empty stomach.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute closure glaucoma. Encourage patient to have an eye exam before starting therapy to see if he is at risk.
- Tell family or caregiver to observe patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Tell patient not to take aspirin or NSAIDs during therapy because they increase the risk of bleeding. If patient takes warfarin, tell her to use bleeding precautions and to notify prescriber at once if bleeding occurs.
- Caution patient to alert all prescribers about vilazodone therapy because of potentially serious drug interactions.
- Advise patient to notify prescriber of any persistent, severe, or unusual adverse reactions.

**vorapaxar**

**Zontivity**

## **Class and Category**

*Pharmacologic class:* Protease activated receptor-1 (PAR-1) inhibitor

*Therapeutic class:* Antiplatelet

*Pregnancy category:* B

## Indications and Dosages

- *To reduce thrombotic cardiovascular events in patients with a history of myocardial infarction or peripheral arterial disease*

### **TABLETS**

**Adults.** 2.08 mg once daily.

## Mechanism of Action

Inhibits thrombin-induced and thrombin receptor agonist peptide-induced platelet aggregation.

## Contraindications

Active pathologic bleeding; history of intracranial hemorrhage, stroke, or transient ischemic attack; hypersensitivity to vorapaxar or its components

## Interactions

### **DRUGS**

*strong CYP3A inducers such as carbamazepine, phenytoin, rifampin, St. John's wort:* Decreased vorapaxar effectiveness

*strong CYP3A inhibitors such as boceprevir, clarithromycin, conivaptan, indinavir, itraconazole, ketoconazole, nelfinavir,*

*posaconazole, ritonavir, saquinavir*: Increased vorapaxar exposure and adverse reactions

## Adverse Reactions

*CNS*: Depression, **intracranial hemorrhage**

*EENT*: Diplopia, oculomotor disturbance, retinal disorder including retinopathy

*GI*: **GI bleeding**

*HEME*: Anemia, **bleeding events that may become severe**, iron deficiency

*SKIN*: Eruptions, exanthema, rash

## Nursing Considerations

- Be aware that vorapaxar is usually prescribed along with other antiplatelet agents such as aspirin and/or clopidogrel.
- Know that vorapaxar should not be given to patients with a history of intracranial hemorrhage, stroke, or transient ischemic attack because of an increased risk for intracranial hemorrhage. The drug should be discontinued in a patient who experiences a stroke while taking vorapaxar.
- Assess patient's bleeding risk before beginning vorapaxar therapy, because vorapaxar increases the risk of bleeding in proportion to the patient's underlying bleeding risk. Factors that may increase the patient's risk of bleeding include the use of certain concomitant drugs such as anticoagulants, chronic nonsteroidal anti-inflammatory drugs, fibrinolytic therapy, selective serotonin reuptake inhibitors, or serotonin-norepinephrine reuptake inhibitors; history of bleeding disorders; low body weight; older age; or reduced hepatic or renal function.
- Know that vorapaxar should not be given to patients with severe hepatic impairment because of increased risk for bleeding.

**WARNING** Monitor patient for bleeding throughout vorapaxar therapy. Suspect bleeding in patient who is hypotensive and has recently undergone coronary angiography, coronary artery bypass graft surgery, percutaneous

coronary intervention, or other surgical procedures. Stop vorapaxar therapy and notify prescriber immediately of suspected or known bleeding. Prepare to support patient according to standard of care, as there is no known treatment to reverse the antiplatelet effect of the drug because of its long half-life. Significant inhibition of platelet aggregation has been known to persist for at least 4 weeks after the drug has been discontinued.

## **PATIENT TEACHING**

- Tell patient to take vorapaxar exactly as prescribed and not to discontinue the drug without discussing it with the prescriber.
- Inform patient that he may bleed or bruise more easily. Stress importance of promptly reporting any excessive, prolonged, or unanticipated bleeding, or blood in the stool or urine.
- Review safety precautions to avoid bleeding events, such as using an electric razor and soft toothbrush.
- Remind patient to inform all dentists and physicians of vorapaxar use prior to any dental procedure or surgery. Emphasize that the dentist or doctor performing the procedure should talk to the prescriber before stopping the drug.
- Tell patient to keep prescriber informed of all dietary supplements, over-the-counter drugs, or prescription drugs he takes.

# **voriconazole**

## **Vfend**

## **Class and Category**

*Pharmacologic class:* Triazole  
*Therapeutic class:* Antifungal  
*Pregnancy category:* D

## Indications and Dosages

- *To treat invasive aspergillosis; to treat serious fungal infections caused by *Scedosporium apiospermum* and *Fusarium* species, including *Fusarium solani*, in patients intolerant of or refractory to other therapy*

### I.V. INFUSION

**Adults.** *Initial:* 6 mg/kg over 1 to 2 hr at no more than 3 mg/kg/hr every 12 hr for two doses followed by 4 mg/kg over 1 to 2 hr at no more than 3 mg/kg/hr every 12 hr for at least 7 days before being switched to an oral form.

### ORAL SUSPENSION, TABLETS

**Adults weighing 40 kg (88 lb) or more.** *Maintenance:* 200 mg every 12 hr, increased to 300 mg every 12 hr, as needed, and taken at least 1 hr before or after a meal.

**Adults weighing less than 40 kg (88 lb).** *Maintenance:* 100 mg every 12 hr, increased to 150 mg every 12 hr, as needed, and taken at least 1 hr before or after a meal.

- *To treat candidemia in nonneutropenic patients and other deep-tissue disseminated *Candida* infections involving the abdomen, bladder wall, kidney, skin, or a wound*

### I.V. INFUSION

**Adults.** *Initial:* 6 mg/kg over 1 to 2 hr at no more than 3 mg/kg/hr every 12 hr for two doses, followed by 3 to 4 mg/kg over 1 to 2 hr at no more than 3 mg/kg/hr every 12

hr and then switched to oral form when feasible. If it's not possible to switch to oral form, IV therapy given for at least 14 days after symptoms resolve or last positive culture, whichever takes longer.

## **ORAL SUSPENSION, TABLETS**

**Adults.** *Maintenance:* 200 mg every 12 hr taken at least 1 hr before or after a meal for at least 14 days after symptoms resolve or last positive culture, whichever takes longer.

➤ *To treat esophageal candidiasis*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 200 mg every 12 hr taken at least 1 hr before or after a meal for at least 14 days and at least 7 days after signs and symptoms resolve.

***DOSAGE ADJUSTMENT*** If patient can't tolerate drug, I.V. maintenance dose may be reduced to 3 mg/kg every 12 hr and oral maintenance dose by 50-mg decrements to at least 200 mg every 12 hr (100 mg every 12 hr for patients weighing less than 40 kg). For use with efavirenz or phenytoin, maintenance dose increased. For patients with mild to moderate hepatic cirrhosis, maintenance dosage reduced.

## **Mechanism of Action**

Prevents fungal ergosterol biosynthesis by inhibiting fungal cytochrome P-450-mediated 14 alpha-lanosterol demethylation. The loss of ergosterol in the fungal cell wall renders the fungal cell inactive.

## **Incompatibilities**

Don't infuse into the same cannula or line with other drugs, including parenteral nutrition, to prevent an increase in subvisible particulate matter. Avoid infusion with blood products and any electrolyte supplements. Don't dilute with 4.2% sodium bicarbonate infusion because the mildly alkaline nature of the diluent causes slight degradation of voriconazole after 24 hours of storage at room temperature.

## Contraindications

Coadministration with long-acting barbiturates, carbamazepine, CYP3A4 substrates (astemizole, cisapride, pimozide, quinidine, or terfenadine), efavirenz, ergot alkaloids, rifabutin, rifampin, ritonavir, sirolimus, or St. John's wort; hypersensitivity to voriconazole or its components; galactose intolerance, glucose-galactose malabsorption, or Lapp lactase deficiency (oral form only contains lactose)

## Interactions

### DRUGS

*alfentanil*: Increased plasma alfentanil level and increased risk of adverse reactions

*benzodiazepines*: Possibly prolonged sedative effect of benzodiazepines

*calcium channel blockers; HMG-CoA reductase inhibitors, such as lovastatin; omeprazole; sirolimus*: Possibly increased plasma levels of these drugs, leading to increased risk of adverse reactions and toxicity

*carbamazepine, long-acting barbiturates, rifampin, ritonavir, St. John's wort*: Decreased plasma voriconazole concentration

*cyclosporine, sirolimus, tacrolimus*: Increased serum concentrations of these drugs and risk of toxicity, especially nephrotoxicity

*CYP3A4 substrates (astemizole, cisapride, pimozide, quinidine, terfenadine)*: Increased plasma levels of these drugs, which may lead to prolonged QT interval and, rarely, torsades de pointes

*efavirenz*: Possibly decreased plasma voriconazole levels and increased plasma efavirenz levels

*ergot alkaloids (dihydroergotamine, ergotamine)*: May increase plasma level of ergot alkaloids, leading to ergotism

*fentanyl and other long-acting opiates metabolized by CYP3A4 such as oxycodone*: Increased plasma level of fentanyl and other long-acting opiates with increased risk of adverse reactions

*everolimus, fluconazole, oral contraceptives*: Increased plasma voriconazole level and risk of toxicity

*HIV protease inhibitors (amprenavir, nelfinavir, ritonavir, saquinavir), non-nucleoside reverse transcriptase inhibitors (delavirdine)*: Possibly inhibited metabolism of voriconazole possibly leading to increased plasma voriconazole levels

*methadone*: Increased plasma level of methadone, possibly leading to toxicity, including QT-interval prolongation

*NSAIDs*: Increased plasma NSAID levels leading to possible increased adverse reactions, including toxicity

*oral contraceptives*: Increased plasma voriconazole level and risk of toxicity ; toxicity; increased plasma levels of oral contraceptives and risk of adverse reactions

*phenytoin*: Decreased plasma level of voriconazole and increased plasma level of phenytoin

*rifabutin*: Increased rifabutin plasma level; decreased voriconazole plasma level

*sulfonylureas*: Possibly increased plasma level of sulfonylureas and increased risk of hypoglycemia

*vinca alkaloids*: Possibly increased risk of neurotoxicity  
*warfarin*: Possibly increased PTT

## Adverse Reactions

**CNS:** Chills, dizziness, fever, hallucinations, headache

**CV:** **Cardiac arrest**, chest pain, hypertension, **hypotension**, peripheral edema, **prolonged QT interval**, tachycardia, **torsades de pointes**, vasodilation, **ventricular tachycardia**

**EENT:** Abnormal or blurred vision, altered or enhanced visual perception, change in color perception, chromatopsia, dry mouth, eye hemorrhage, photophobia, visual disturbances

**GI:** Abdominal pain, cholestatic jaundice, diarrhea, elevated liver enzymes, **fulminant hepatic failure**, **hepatitis**, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Abnormal kidney function, **acute renal failure**, elevated serum creatinine level

**HEME:** Anemia, **leukopenia**, **pancytopenia**, **thrombocytopenia**

**MS:** Fluorosis, periostitis, skeletal pain

**RESP:** Respiratory disorders

**SKIN:** **Erythema multiforme**, maculopapular rash, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** **Anaphylaxis**, elevated alkaline phosphatase, **hypokalemia**, **hypomagnesemia**, **sepsis**

## Nursing Considerations

- Use voriconazole cautiously in patients hypersensitive to other azoles and in patients at risk for proarrhythmic events (such as those receiving cardiotoxic chemotherapy or concomitant drug therapy known to prolong

QT interval, or those who have acquired or congenital QT prolongation, cardiomyopathy, hypokalemia, sinus bradycardia, or symptomatic arrhythmias [existing]). because drug may prolong the QT interval. Know that calcium, magnesium, and potassium imbalances should be corrected before starting voriconazole therapy as well as any time an imbalance occurs during voriconazole therapy. Monitor patient's electrolyte balance closely.

- Determine if patient has any problems with galactose intolerance, glucose-galactose malabsorption, or Lapp lactase deficiency before starting therapy because voriconazole tablets contain lactose and shouldn't be given to patients with these conditions.
- Obtain specimens for fungal culture and other relevant laboratory studies (including histopathology), as ordered, before giving first dose. Expect to begin drug before test results are known.
- Assess patient's liver function, including bilirubin, as ordered, at the start of voriconazole therapy and at least weekly for the first month of treatment then monthly thereafter because, although uncommon, drug has caused serious hepatic reactions, including fatalities. Be aware that drug may be discontinued if liver abnormalities occur.
- For I.V. infusion, reconstitute powder with 19 ml water for injection to obtain 20 ml of concentrate containing 10 mg/ml voriconazole. To make sure exact amount of water is injected into vial, use a standard 10-ml nonautomated syringe. Shake vial until all powder is dissolved. Further dilute so final concentration is no less than 0.5 mg/ml and no more than 5 mg/ml. This requires withdrawing and discarding at least an equal volume of diluent from infusion bag or bottle before instillation of concentrate.
- Discard partially used vials after mixing. If infusion isn't administered immediately, store at 2° to 8°C (37° to 46°F) for no longer than 24 hours.
- Administer I.V. infusion over 1 to 2 hours at no more than 3 mg/kg/hr.
- Monitor renal function, especially serum creatinine level, when giving I.V. form of voriconazole because drug may accumulate in body when creatinine clearance is less than 50 ml/min, increasing the risk of adverse reactions.

**WARNING** Observe patient receiving I.V. voriconazole closely for anaphylactoid-type reactions, such as chest tightness, dyspnea, faintness, fever, flushing, nausea, pruritus, rash, sweating, and tachycardia, which may occur immediately after starting infusion. Stop infusion

if these reactions occur, and notify prescriber immediately.

- Monitor patient closely throughout therapy for rash, which may indicate a serious cutaneous reaction, such as Stevens–Johnson syndrome. If rash occurs, notify prescriber, and expect that voriconazole may be discontinued.
- Monitor cyclosporine, tacrolimus, and warfarin closely for elevated levels when voriconazole is given with any of these drugs.
- Monitor diabetic patients also taking sulfonylureas closely for hypoglycemia, and check blood glucose levels regularly.
- Keep in mind voriconazole dosage will need to be adjusted when given with efavirenz or phenytoin. Expect to monitor plasma phenytoin level and observe patient closely for adverse reactions.
- Assess patient’s visual function, including color perception, visual acuity, and visual field, if voriconazole therapy continues longer than 28 days.
- Monitor patient closely for pancreatitis, especially if patient is a child or has risk factors for acute pancreatitis, such as recent chemotherapy or hematopoietic stem cell transplantation.
- Report skeletal pain to prescriber and expect skeletal x-rays to be done. If fluorosis or periostitis is found, anticipate voriconazole therapy to be discontinued.

## **PATIENT TEACHING**

- Instruct patient taking oral voriconazole to take oral suspension or tablets at least 1 hour before or 1 hour after a meal.
- Inform female patient of possible fetal risk, and emphasize need to avoid pregnancy. Tell her to use effective contraception during therapy and to notify prescriber immediately if pregnancy is suspected.
- Caution patient not to drive at night and to avoid hazardous activities because drug may cause visual disturbances, including blurring or photophobia.
- Advise patient to avoid exposure to direct sunlight or UV light and to wear sunscreen when outdoors.

# vortioxetine hydrobromide

**Trintellix**

## Class and Category

*Pharmacologic class:* Serotonin modulator

*Therapeutic class:* Antidepressant

*Pregnancy category:* C

## Indications and Dosages

➤ *To treat major depressive disorder (MDD)*

### **TABLETS**

**Adults.** *Initial:* 10 mg once daily, then increased to 20 mg once daily, as tolerated. *Maximum:* 20 mg once daily.

***DOSAGE ADJUSTMENT*** For patients who cannot tolerate higher doses, dosage may be decreased down to 5 mg once daily. For patients taking strong CYP inducers, such as carbamazepine, phenytoin, or rifampin concurrently for longer than 14 days, dosage increased up to three times the original dose and when inducer is discontinued, dosage decreased to original level within 14 days. For patients taking strong CYP2D6 inhibitors such as bupropion, fluoxetine, paroxetine, or quinidine concurrently, dosage reduced by one half, and when inhibitor is discontinued, dosage increased to original level within 14 days. For patients who are known CYP2D6 poor metabolizers, maximum dosage is 10 mg once daily.

# Mechanism of Action

Enhances serotonergic activity in the central nervous system through inhibiting the reuptake of serotonin. Enhanced serotonergic activity is thought to relieve symptoms of depression.

# Contraindications

Hypersensitivity to vortioxetine or its components; use within 14 days of a MAO inhibitor, including intravenous methylene blue and linezolid

# Interactions

## DRUGS

*aspirin, NSAIDs, warfarin, and other anticoagulants:*

Increased risk of bleeding

*buspirone, MAO inhibitors, SNRIs, SSRIs, tramadol,*

*triptans, tryptophans:* Increased risk of serotonin toxicity

*CYP2D6 inducers (strong) such as carbamazepine,*

*phenytoin, rifampin:* Decreased plasma vortioxetine levels with possible decreased effectiveness

*CYP2D6 inhibitors (strong) such as bupropion, fluoxetine,*

*paroxetine, and quinidine:* Increased plasma vortioxetine levels with increased risk of adverse reactions

# Adverse Reactions

**CNS:** Abnormal dreams, activation of hypomania/mania, dizziness, **seizures**, **serotonin syndrome**, **suicidal ideation**, vertigo

**EENT:** Altered taste, angle-closure glaucoma, dry mouth

**GI:** **Acute pancreatitis**, constipation, diarrhea, dyspepsia, flatulence, nausea, vomiting

**GU:** Decreased libido, sexual performance, or sexual satisfaction

**HEME:** **Abnormal bleeding**

**RESP:** Difficulty breathing

**SKIN:** Flushing, pruritus, rash, urticaria

**Other:** **Hyponatremia**, weight gain

## Nursing Considerations

- Be aware that at least 14 days should elapse between discontinuing a MAO inhibitor used to treat psychiatric disorders and initiation of vortioxetine therapy to avoid risk of patient developing serotonin syndrome. Also, know that at least 21 days should elapse after vortioxetine is discontinued and therapy with a MAO inhibitor used to treat a psychiatric disorder is begun.
- Expect dosage to be decreased to 10 mg once daily for 1 week before vortioxetine is discontinued to avoid patient experiencing dizziness, headaches, mood swings, including muscle tension, runny nose, or sudden outbursts of anger that may occur in the first week of abrupt discontinuation of the drug.
- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Watch for mania, which may result from use of any antidepressant in a susceptible patient.
- Monitor patient closely for evidence of GI bleeding, especially if patient also takes a drug known to cause GI bleeding, such as aspirin, a NSAID, warfarin, or other anticoagulants.

**WARNING** Monitor patient closely for serotonin syndrome exhibited by agitation, coma, diarrhea, hallucinations, hyperreflexia, hyperthermia, incoordination, labile blood pressure, nausea, or vomiting. Notify prescriber immediately because serotonin syndrome may be life-threatening, and provide supportive care.

- Monitor patient's serum sodium level because hyponatremia has occurred with use of serotonergic drugs, including vortioxetine. Patients at greater risk include the elderly and patients taking diuretics or who are volume-depleted. Report signs and symptoms of hyponatremia, such as confusion, difficulty concentrating, headache, memory impairment, unsteadiness, or weakness. If left untreated, coma, death, hallucinations, respiratory arrest, seizures, or syncope may occur.

## **PATIENT TEACHING**

- Instruct patient to take drug exactly as prescribed and to alert prescriber with concerns.
- Inform patient that nausea is the most common side effect of vortioxetine therapy, and it commonly occurs within the first week of treatment.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute closure glaucoma. Encourage patient to have an eye exam before starting therapy to see if he is at risk.
- Tell family or caregiver to observe patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Warn patient not to discontinue drug abruptly.
- Advise patient to inform all prescribers of vortioxetine therapy.
- Emphasize importance of reporting any persistent, severe, or sudden symptoms to prescriber.
- Alert patients about risk of bleeding when taking drugs known to increase risk of bleeding, such as aspirin, blood thinners, or NSAIDs.
- Tell patient and caregivers to report any signs of abnormal behavior.
- Inform elderly patient or patient who is taking drugs, such as diuretics, that cause him to be dehydrated of the risk of a low sodium level; tell patient to alert prescriber if he experiences new or sudden onset of symptoms.
- Advise patient to seek emergency medical attention if an allergic reaction such as difficulty breathing, hives, rash, or swelling occurs.
- Instruct female patients of childbearing age to notify prescriber if pregnancy occurs or is suspected.
- Tell patient to inform all prescribers of vortioxetine therapy and not to take any over-the-counter medications, including herbal products, without prescriber knowledge.

# warfarin sodium

## Coumadin

### Class and Category

*Pharmacologic class:* Coumarin derivative

*Therapeutic class:* Anticoagulant

*Pregnancy category:* X

### Indications and Dosages

- *To prevent or treat pulmonary embolism; recurrent MI; thromboembolic complications from atrial fibrillation, heart valve replacement, or MI; and venous thrombosis (and its extension)*

### TABLETS

**Adults.** *Initial:* 2 to 5 mg daily for 2 to 4 days. *Usual:* 2 to 10 mg daily based on target INR and PT results. *Maximum:* Determined by target INR and PT results, as prescribed.

### I.V. INJECTION

**Adults.** *Initial:* 2 to 5 mg daily infused over 1 to 2 min. *Usual:* 2 to 10 mg daily infused over 1 to 2 min based on target INR and PT results. *Maximum:* Determined by target INR and PT results, as prescribed.

***DOSAGE ADJUSTMENT*** For Asian, debilitated, or elderly patients, dosage reduced and then adjusted based on INR and PT results.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	24 hr	3-4 days	2-5 days
I.V.	Unknown	3-4 days	2-5 days

## **Mechanism of Action**

Interferes with the liver's ability to synthesize vitamin K-dependent clotting factors, depleting clotting factors II (prothrombin), VII, IX, and X. This action, in turn, interferes with the clotting cascade. By depleting vitamin K-dependent clotting factors and interfering with the clotting cascade, warfarin prevents coagulation.

## **Incompatibilities**

Don't mix warfarin in solution with amikacin sulfate, epinephrine hydrochloride, metaraminol tartrate, oxytocin, promazine hydrochloride, tetracycline hydrochloride, or vancomycin hydrochloride.

## **Contraindications**

Bleeding or bleeding tendencies; blood dyscrasias; cerebral or dissecting aneurysm; cerebrovascular hemorrhage; diverticulitis; eclampsia or preeclampsia; history of warfarin-induced necrosis; hypersensitivity to warfarin or its components; malignant or severe uncontrolled hypertension; malnutrition and emaciation; mental state or condition that leads to lack of patient cooperation, or unsupervised situation; pericardial effusion; pericarditis; polyarthritis; pregnancy except in women with mechanical heart valves, who are at high risk of thromboembolism; prostatectomy; recent or planned neurosurgery, ophthalmic surgery, or spinal puncture; severe hepatic or renal disease

# Interactions

## DRUGS

*acetaminophen, agrimony, aminoglycosides, amiodarone, androgens, argatroban, beta blockers, bivalirudin, capecitabine, cephalosporins, chloral hydrate, chloramphenicol, chlorpropamide, cimetidine, clofibrate, corticosteroids, cyclophosphamide, dextrothyroxine, diflunisal, disulfiram, erythromycin, ezetimibe, fluconazole, gemfibrozil, glucagon, hydantoins, ifosfamide, influenza virus vaccine, isoniazid, ketoconazole, lepirudin, loop diuretics, lovastatin, metronidazole, miconazole, mineral oil, moricizine, nalidixic acid, NSAIDs, omeprazole, penicillins, phenylbutazones, propafenone, propoxyphene, quinidine, quinine, quinolones, salicylates, streptokinase, sulfamethoxazole-trimethoprim, sulfinpyrazone, sulfonamides, tamoxifen, tetracyclines, thyroid hormones, urokinase, valdecoxib, vitamin E:* Increased anticoagulant effect of warfarin, increased risk of bleeding

*aminogluthethimide, barbiturates, carbamazepine, cholestyramine, dicloxacillin, estrogens, ethchlorvynol, etretinate, glutethimide, griseofulvin, multivitamins (selected ones), nafcillin, oral contraceptives, rifampin, spironolactone, sucralfate, thiazide diuretics, trazodone, vitamin C, vitamin K:* Decreased anticoagulant effect of warfarin

*atorvastatin, pravastatin:* Increased or decreased anticoagulant effect of warfarin

*herbal remedies (including bromelains, danshen, dong quai, garlic, ginkgo biloba, and ginseng):* Increased anticoagulant effect of warfarin, increased risk of bleeding

*I.V. lipid emulsion, other medical products that contain soybean oil:* Possibly decreased vitamin K absorption and increased anticoagulant effect of warfarin

*nicotine patch*: Altered response to warfarin

## **FOODS**

*certain enteral feedings, vitamin K-rich foods*: Decreased warfarin effects

## **ACTIVITIES**

*alcohol use*: Increased risk of hypopro-thrombinemia  
*smoking, smoking cessation aids*: Altered response to warfarin

## **Adverse Reactions**

**CNS**: **Coma**, **intracranial hemorrhage**, loss of consciousness, syncope, weakness

**CV**: Angina, calcium uremic arteriolopathy (calciphylaxis), chest pain, **hypotension**

**EENT**: Epistaxis, intraocular hemorrhage

**GI**: Abdominal cramps and pain, diarrhea, **hepatitis**, jaundice, nausea, vomiting

**GU**: Hematuria, vaginal bleeding (abnormal)

**HEME**: Anemia, **potentially fatal hemorrhage**

**SKIN**: Alopecia, ecchymosis, petechiae, pruritus, purple-toe syndrome, tissue necrosis

**Other**: **Anaphylaxis**

## **Nursing Considerations**

- Ensure that women of childbearing age has a negative pregnancy test result before warfarin therapy is initiated because drug may cause fetal harm even in the first trimester.
- Reconstitute parenteral warfarin just before administration with 2.7 ml sterile water for injection to yield 2 mg/ml. Then give slowly over 1 to 2 minutes through peripheral I.V.

- Expect to give another parenteral anticoagulant, such as enoxaparin or heparin, with oral warfarin for at least 3 days, or until desired response occurs, before giving warfarin only.
- Avoid I.M. injections during warfarin therapy, if possible, because they can result in bleeding, bruising, and hematoma.
- Monitor INR (daily in acute care setting) and assess for therapeutic effects, as prescribed. Therapeutic INR levels are 2.0 to 3.0 for bioprosthetic heart valve, nonvalvular atrial fibrillation, and venous thromboembolism, and 2.5 to 3.5 after MI and for mechanical heart valve.
- Monitor patient with hepatic impairment closely for bleeding, because hepatic impairment decreases metabolism of warfarin and impairs synthesis of clotting factors. Expect to monitor patient's INR more frequently.
- Expect treatment to last up to 12 weeks for bioprosthetic heart valve, 1 to 3 months for nonvalvular atrial fibrillation or venous thromboembolism, and for rest of life after MI and for mechanical heart valve replacement.

**WARNING** Be aware of the increased risk for intracranial hemorrhage if patient has cerebral ischemia (such as recent transient ischemic attack or minor ischemic stroke) and INR of 3 to 4.5. As prescribed, withhold next warfarin dose and give vitamin K, as ordered, if INR exceeds 4 because of the risk of bleeding.

- Assess for occult bleeding if patient receives I.V. lipid emulsion or other medical product that contains soybean oil. Such products can decrease vitamin K absorption and increase warfarin's anticoagulant effect.
- Monitor patient for persistent, severe, sudden, or unusual signs and symptoms, as warfarin therapy may cause many adverse reactions, including calciphylaxis, a syndrome of blood clots, calcification of blood vessels, and skin necrosis. If diagnosed, expect warfarin therapy to be discontinued and alternative anticoagulation therapy prescribed.

## **PATIENT TEACHING**

- Explain that warfarin therapy aims to prevent thrombosis by decreasing clotting ability while avoiding the risk of spontaneous bleeding.

- Instruct patient to take drug exactly as prescribed at the same time each evening.
- Advise patient if a dose is missed to take it as soon as it is remembered on the same day, but not to take a double dose the next day to make up for it.
- Urge patient to keep weekly follow-up appointments for blood tests after discharge until PT and INR levels are stabilized.
- Advise patient to avoid alcohol during warfarin therapy.
- Urge patient to take precautions against bleeding, such as using an electric shaver and a soft-bristled toothbrush. Advise him to continue these precautions for 2 to 5 days after therapy stops, as directed, because anticoagulant effect may persist during this time.
- Caution patient to avoid activities that could cause traumatic injury and bleeding.
- Advise patient to avoid drastic changes in dietary habits, such as eating large amounts of leafy, green vegetables. Explain that dark green, leafy vegetables contain vitamin K that counteracts the effects of warfarin.
- Urge patient to notify prescriber immediately about unusual bleeding and any unexplained symptoms, such as abnormal vaginal bleeding; dizziness; easy bruising; gum bleeding; headache; nosebleeds; prolonged bleeding from cuts; red, black, or tarry stool; red or dark brown urine; swelling; and weakness.
- Advise patient to consult prescriber before taking other drugs—including OTC drugs and herbal remedies—during therapy. Also instruct him to not discontinue any drug, including over-the-counter drugs and herbal products he takes regularly, without consulting the prescriber.
- Instruct female patient of childbearing age to use an effective contraceptive during warfarin therapy and for at least 1 month after warfarin has been discontinued. Stress importance because drug may cause fetal harm. Also tell patient to notify prescriber immediately if pregnancy occurs or is suspected.
- Tell patient who is breastfeeding to monitor her infant for bleeding or bruising and to notify prescriber immediately if either occurs.

**WARNING** Tell patient to contact prescriber immediately if he experiences pain and discoloration of the skin mostly on areas of the body with a high fat content, such as abdomen, breasts, buttocks, hips, and thighs or if he experiences any unusual symptoms. Explain that drug

may cause reversible purple-toe syndrome but that this syndrome isn't harmful.

- Urge patient to carry medical identification that reveals he's taking warfarin.
- Tell patient to inform all dentists and healthcare professionals that he is taking warfarin, especially before any procedure or surgery, including dental, is performed.

# X Y Z

**zafirlukast**

**Accolate**

## Class and Category

*Pharmacologic class:* Leukotriene receptor antagonist

*Therapeutic class:* Antiasthmatic

*Pregnancy category:* B

## Indications and Dosages

➤ *To prevent or treat chronic asthma*

### **TABLETS**

**Adults and children over age 11.** 20 mg twice daily.

**Children ages 5 to 11.** 10 mg twice daily.

Route	Onset	Peak	Duration
P.O.	1 wk	Unknown	Unknown

## Mechanism of Action

Inhibits the selective binding of cysteinyl leukotrienes (arachidonic acid derivatives that usually mediate inflammation in asthma and other inflammatory disorders)

by competitively blocking receptor sites. This action causes bronchial relaxation and decreases bronchial hyperresponsiveness, eosinophil movement, mucus secretion, and vascular leakage.

## Contraindications

Hepatic impairment including hepatic cirrhosis, hypersensitivity to zafirlukast or its components

## Interactions

### DRUGS

*alprazolam, amitriptyline, calcium channel blockers, carbamazepine, citalopram, corticosteroids, cyclosporine, diazepam, diclofenac, ibuprofen, imipramine, irbesartan, lidocaine, lovastatin, midazolam, phenytoin, quinidine, simvastatin, tolbutamide, tolterodine, triazolam:* Inhibited metabolism and, possibly, additive adverse effects of these drugs

*aspirin:* Increased blood zafirlukast level

*erythromycin, terfenadine:* Decreased response to zafirlukast

*sildenafil:* Increased adverse sildenafil effects

*theophylline:* Decreased zafirlukast level; possibly increased theophylline levels

*warfarin:* Prolonged PT

### FOODS

*any food:* Possibly decreased bioavailability of zafirlukast

## Adverse Reactions

**CNS:** Asthenia, depression, dizziness, fever, headache, insomnia, malaise

**CV:** Edema, vasculitis

**GI:** Abdominal pain, diarrhea, edema, elevated liver enzymes, **hepatic failure**, **hepatitis**, hyperbilirubinemia, indigestion, nausea, vomiting

**HEME:** **Agranulocytosis**, **bleeding**, eosinophilia

**MS:** Arthralgia, back pain, myalgia

**RESP:** Eosinophilic pneumonia

**SKIN:** Bruising, pruritus, rash, urticaria

**Other:** **Angioedema**, generalized pain, **hypersensitivity reactions**, infections

## Nursing Considerations

- Know that zafirlukast shouldn't be used to treat bronchospasm during an acute asthma attack or status asthmaticus; it can't relieve symptoms quickly enough.
- Assess respiratory depth, quality, and rate, as well as breath sounds, before and during treatment to evaluate response to therapy.
- Be aware that if patient is being weaned from corticosteroids while taking zafirlukast, she should be monitored for Churg-Strauss syndrome—a rare allergic reaction characterized by eosinophilia, fever, myalgia, and weight loss—for cardiac complications, neuropathy, and worsening pulmonary symptoms.

## PATIENT TEACHING

- Instruct patient to take drug exactly as prescribed, in evenly spaced doses, every day, even during acute exacerbations and symptom-free periods.
- Instruct patient to take drug on an empty stomach at least 1 hour before meals, or 2 hours after.
- Urge patient to continue using prescribed rescue inhalants for acute asthma attacks.

- Teach patient how to use peak-flow meter to monitor pulmonary function.
- Tell patient to report immediately any evidence of liver dysfunction, such as anorexia, fatigue, flu-like symptoms, jaundice, lethargy, nausea, right upper-quadrant abdominal pain, or pruritus.

# zaleplon

## Sonata

### Class, Category, and Schedule

*Pharmacologic class:* Pyrazolopyrimidine

*Therapeutic class:* Hypnotic

*Pregnancy category:* C

*Controlled substance schedule:* IV

### Indications and Dosages

➤ *Short-term treatment of insomnia*

#### CAPSULES

**Adults up to age 65.** 10 mg daily at bedtime, as needed, for up to 35 days. *Usual:* 10 mg daily at bedtime for 7 to 10 days. *Maximum:* 20 mg daily.

***DOSAGE ADJUSTMENT*** For patients who are debilitated, elderly, have hepatic impairment or low weight, or take cimetidine, dosage reduced to 5 mg daily.

Route	Onset	Peak	Duration
P.O.	30 min	Unknown	4 hr

# Mechanism of Action

Selectively binds with type 1 benzodiazepine (BZ1 or  $\omega_1$ ) receptors on the gamma-aminobutyric acid-A receptor complex. This binding produces muscle relaxation and sedation as well as antianxiety and anticonvulsant effects.

# Contraindications

Hypersensitivity to zaleplon or its components

# Interactions

## DRUGS

*amitriptyline; amoxapine; azatadine; benzodiazepines; brompheniramine; chlorpheniramine; clemastine; clomipramine; clozapine; cyproheptadine; dexchlorpheniramine; diphenhydramine; doxepin; entacapone; haloperidol; hydroxyzine; imipramine; mirtazapine; molindone; nefazodone; nortriptyline; olanzapine; opioid analgesics; other anxiolytics, hypnotics and sedatives; phenindamine; phenothiazines; pimozide; pramipexole; promethazine; quetiapine; risperidone; ropinirole; thioridazine; trazodone; trimipramine; tripelennamine: Possibly additive CNS depression carbamazepine, phenobarbital, phenytoin, rifampin:*  
Reduced zaleplon effects  
*cimetidine: Increased blood zaleplon level*  
*flumazenil: Reversal of zaleplon's sedation*

## FOODS

*high-fat foods:* Prolonged absorption time and reduced effectiveness of zaleplon

## ACTIVITIES

*alcohol use:* Increased CNS depression

## Adverse Reactions

**CNS:** Amnesia, anxiety, complex behaviors (such as sleep driving), depression, dizziness, drowsiness, fever, hallucinations, hypertonia, insomnia, nightmares, paresthesia, **seizures**, **suicidal ideation**, tremor, vertigo

**EENT:** Dry mouth, gingivitis, glossitis, mouth ulcers, stomatitis, **throat tightness**

**GI:** Anorexia, colitis, constipation, eructation, esophagitis, flatulence, gastritis, gastroenteritis, increased appetite, indigestion, **melena**, nausea, **rectal bleeding**, vomiting

**MS:** Back pain

**RESP:** Dyspnea

**SKIN:** Photosensitivity, pruritus, rash

**Other:** **Anaphylaxis**, **angioedema**, physical and psychological dependence

## Nursing Considerations

- Give zaleplon just before bedtime because its onset of action is rapid.
- Avoid giving drug with or after a heavy, high-fat meal because decreased absorption may reduce drug's effects.
- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Monitor patient for signs of drug abuse because zaleplon has an abuse potential similar to that of benzodiazepines and benzodiazepine-like hypnotics.

**WARNING** Monitor patient closely for hypersensitivity reactions, such as dyspnea, nausea, throat tightness, vomiting, and swelling. If present, discontinue zaleplon immediately, notify prescriber, and provide supportive care.

## **PATIENT TEACHING**

- Explain that zaleplon is intended for short-term use. Advise against using it for any condition other than insomnia.
- Caution patient against exceeding prescribed dosage.
- Instruct patient to take zaleplon immediately before bedtime or right after having trouble falling asleep because of drug's rapid onset of action.
- Teach patient alternative measures for relaxation and sleep induction.
- Advise patient to consult prescriber before taking other CNS depressants.
- Urge patient to avoid alcohol during zaleplon therapy because it increases risk of abnormal behaviors, such as sleep driving.
- Warn patient that zaleplon contains FD & C Yellow No. 5 (tartrazine), which can cause an allergic reaction, especially in those with an aspirin sensitivity. Instruct patient to immediately report allergic reactions, such as difficulty breathing or rash, to prescriber.
- Instruct patient to notify prescriber if inability to sleep continues. Dosage may need to be adjusted.
- Instruct patient to stop taking zaleplon and seek emergency care if she has abnormal swelling, nausea, throat tightness, trouble breathing, or vomiting.
- Explain that drug may cause abnormal behaviors during sleep, such as driving a car, eating, having sex, or talking on the phone without any recall of the event. If family notices any such behavior or patient sees evidence of such behavior upon awakening, prescriber should be notified.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.

# zidovudine

## Retrovir

### Class and Category

*Pharmacologic class:* Nucleoside reverse transcriptase inhibitor

*Therapeutic class:* Antiretroviral

*Pregnancy category:* Not classified

### Indications and Dosages

- *As adjunct to treat human immunodeficiency viral type (HIV-1) infection*

### CAPSULES, SYRUP

**Adults.** 300 mg twice daily.

**Children less than 18 years weighing 30 kg (66 lb) or more.** 300 mg twice daily or 200 mg three times daily.

Alternatively, 240 mg/m<sup>2</sup> body surface area (BSA) twice daily or 160 mg/m<sup>2</sup> BSA three times daily. *Maximum:* 600 mg daily.

**Infants at least 4 weeks old and children less than 18 years weighing 9 kg (19.8 lb) to less than 30 kg (66 lb).** 9 mg/kg twice daily or 6 mg/kg three times daily.

Alternatively, 240 mg/m<sup>2</sup> body surface area (BSA) twice daily or 160 mg/m<sup>2</sup> BSA three times daily. *Maximum:* 300 mg twice daily.

**Infants at least 4 weeks old and weighing at least 4 kg (8.8 lb) but less than 9 kg (19.8 lb).** 12 mg/kg twice

daily or 8 mg/kg three times daily. Alternatively, 240 mg/m<sup>2</sup> BSA twice daily or 160 mg/m<sup>2</sup> BSA three times daily. *Maximum:* 300 mg twice daily.

## **I.V. INFUSION**

**Adults.** 1 mg/kg at a constant rate over 1 hr every 4 hr.

➤ *To prevent maternal-fetal HIV-1 transmission*

## **CAPSULES, SYRUP**

**Pregnant women at greater than 14 weeks of pregnancy.** 100 mg five times daily until start of labor.

## **I.V. INFUSION**

**Pregnant women during labor and delivery.** 2 mg/kg infused over 1 hr followed by a continuous I.V. infusion of 1 mg/kg/hr until umbilical cord is clamped.

## **SYRUP**

**Neonate 12 hr after birth.** 2 mg/kg every 6 hr for 6 wk.

## **I.V. INFUSION**

**Neonate 12 hr after birth.** 1.5 mg/kg infused over 30 min, every 6 hr for 6 wk.

***DOSAGE ADJUSTMENT*** For adult patients on dialysis or who have a creatinine clearance of less than 15 ml/min, oral dosage reduced to 100 mg every 6 to 8 hr and the intravenous dosage interval increased to every 6 to 8 hr.

## **Mechanism of Action**

After being phosphorylated to its active metabolite, the metabolite inhibits the DNA- and RNA-dependent

polymerase activities of HIV-1 reverse transcriptases via DNA chain termination after incorporation of the nucleotide analogue into viral DNA. This destroys activity of the HIV-1 viruses.

## Contraindications

Hypersensitivity to zidovudine or its components

## Interactions

### DRUGS

*bone marrow suppressive or cytotoxic agents, ganciclovir, interferon alfa, ribavirin:* Possibly increased hematologic toxicity of zidovudine

*doxorubicin, nucleoside analogues affecting DNA replication such as ribavirin, stavudine:* Antagonistic relationship between the two drugs

## Adverse Reactions

**CNS:** Anxiety, asthenia, chills, confusion, decreased reflexes, depression, dizziness, fatigue, headache, insomnia, irritability, loss of mental acuity, malaise, mania, nervousness, neuropathy, paresthesia, **seizures**, somnolence, syncope, tremor, vertigo

**CV:** **Cardiomyopathy**, chest pain, **congestive heart failure**, **ECG abnormalities**, edema, left ventricular dilation, vasculitis

**EENT:** Amblyopia; ear discharge, erythema, pain, or swelling; hearing loss; macular edema; mouth ulcers; nasal congestion or discharge; oral mucosa pigmentation; photophobia; rhinitis; sinusitis; stomatitis; taste perversion

**ENDO:** Cushingoid appearance, fat redistribution, gynecomastia

**GI:** Abdominal cramps or pain, anorexia, constipation, diarrhea, dyspepsia, dysphagia, elevated liver or pancreatic enzymes, flatulence, **hepatic decompensation, hepatitis, hyperbilirubinemia, jaundice, nausea, pancreatitis, severe hepatomegaly with steatosis**, splenomegaly, vomiting

**GU:** Hematuria, urinary frequency or hesitancy

**HEME:** Anemia, **aplastic anemia, granulocytopenia, hemolytic anemia, leukopenia**, macrocytosis, **neutropenia, pancytopenia with marrow hypoplasia, pure red cell aplasia, thrombocytopenia**

**MS:** Arthralgia, back pain, elevated CPK and LDH levels, musculoskeletal pain, muscle spasm, myalgia, myopathy, myositis, **rhabdomyolysis**

**RESP:** Abnormal breath sounds, cough, dyspnea, wheezing

**SKIN:** Diaphoresis, pigmentation changes in nail and skin, pruritus, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis, angioedema**, flu-like symptoms, generalized pain, intravenous site irritation or pain, **lactic acidosis**, lymphadenopathy, weight loss

## Nursing Considerations

- Use zidovudine cautiously in patients with hepatic dysfunction, including liver cirrhosis, because of potential for hepatic dysfunction during zidovudine therapy.
- Be aware that dosing regimen for the prevention of maternal-fetal HIV-1 transmission includes three phases. First, oral zidovudine is given to the mother beginning after 14 weeks of pregnancy and continued throughout the remainder of pregnancy, stopping at the start of labor. Then drug is given intravenously to the mother during labor until the umbilical cord is cut. Lastly, drug is then given to the newborn beginning 12 hours after birth and continued for 6 weeks. Use an appropriate-sized syringe with 0.1-ml graduation to ensure dosing of the syrup formulation in neonates.

- Know that pediatric dosage is based upon body weight in kg or alternatively on BSA. In some cases, the dosage calculated by body weight will not be the same as that calculated by BSA.
- Dilute intravenous injection solution by adding drug to 5% dextrose injection solution to achieve a concentration no greater than 4 mg/ml. Use within 8 hours if left at room temperature and 24 hours if refrigerated.
- Be aware that zidovudine injection solution should never be given as a bolus injection or by rapid infusion, nor should it be administered intramuscularly.
- Be aware that the vial stoppers on zidovudine injection bottles contain natural rubber latex and could cause a hypersensitivity reaction if touched by someone with a latex allergy.

**WARNING** Know that lactic acidosis and severe hepatomegaly with steatosis have occurred with zidovudine therapy, and death has occurred in some patients. Risk factors include presence of obesity, prolonged nucleoside exposure, and being a woman. However, know that lactic acidosis and severe hepatomegaly with steatosis have also occurred in patients with no known risk factors. Expect drug to be discontinued in any patient who develops clinical or laboratory findings suggestive of lactic acidosis or pronounced hepatotoxicity, even in the absence of marked transaminase elevations.

- Monitor patient's hematologic status closely during zidovudine therapy, as ordered. Know that if patient's hemoglobin falls to less than 7.5 g/dl or the reduction is greater than 25% of baseline and/or granulocyte count falls to less than 750 cells/mm<sup>3</sup> or the reduction is greater than 50% of baseline, notify prescriber and expect zidovudine therapy to be withheld until marrow recovery occurs. Even with marrow recovery, adjunctive supportive measures such as epoetin alfa might be required when zidovudine therapy is restarted.
- Know that coadministration of ribavirin and zidovudine is not advised, because ribavirin exacerbates the development of zidovudine-induced anemia.
- Be aware that patients receiving interferon alfa and/or ribavirin in addition to zidovudine should be monitored closely for treatment-associated toxicities, especially anemia, hepatic decompensation, and

neutropenia. Dosage reduction or discontinuation of interferon alfa, ribavirin, or both may be required if zidovudine toxicities become serious.

- Be aware that prolonged therapy increases the risk of myopathy and myositis.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including zidovudine. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.
- Observe patient for redistribution of body fat, including breast enlargement, central obesity, development of buffalo hump, facial wasting, and peripheral wasting, which may produce a cushingoid-type appearance.

## PATIENT TEACHING

- Instruct parents or caregivers to take extra care in measuring dosage when using syrup that will be given to babies and children, to avoid dosage errors. Caution them to use an appropriately sized syringe with 0.1-ml graduation to ensure accurate dosing of the syrup formulation. Do not use the common household teaspoon.
- Tell patient that if she misses a dose of zidovudine, she should take it as soon as she remembers, but should not double the next dose or take more than prescribed.

**WARNING** Instruct patient to seek immediate medical attention if she experiences a serious allergic reaction, such as having difficulty breathing, hives, or swelling of her face, lips, tongue, or throat.

- Inform patient that periodic laboratory studies will have to be performed and that compliance with these appointments is essential for early detection of adverse reactions. If toxicity develops, inform her that she may need transfusions or zidovudine to be discontinued.
- Alert patient that fat accumulation and redistribution may occur during zidovudine therapy.

**WARNING** Alert patient that severe conditions may develop while taking zidovudine. Encourage her to stop taking drug and seek medical attention immediately if she experiences any persistent, severe, or unusual symptoms.

- Advise patient to inform all prescribers of zidovudine therapy.

**WARNING** Inform patient that zidovudine may cause lactic acidosis, which if not treated, could be fatal. Tell patient to seek immediate medical attention if she develops breathing difficulty, cold or numb feeling in her arms and legs, dizziness, fast or uneven heart rate, muscle pain or weakness, nausea, vomiting, or any other unexpected or unusual signs or symptoms.

- Tell mothers that breastfeeding should not be done during zidovudine therapy.

**zinc acetate**

**Galzin**

**zinc chloride**

**zinc gluconate**

**Orazinc**

**zinc sulfate**

# Orazinc, Verazinc, Zinc 15, Zinc-220, Zinca-Pak, Zincate

## Class and Category

*Pharmacologic class:* Trace element, mineral

*Therapeutic class:* Nutritional supplement

*Pregnancy category:* A (oral), C (I.V.)

## Indications and Dosages

- *To prevent zinc deficiency based on recommended daily allowances*

### **CAPSULES, E.R. TABLETS, LOZENGES, TABLETS**

**Men and boys age 14 and over.** 11 mg daily.

**Women.** 8 mg daily.

**Pregnant women.** 11 mg daily.

**Breastfeeding women.** 12 mg daily.

**Adolescent females ages 14 to 18.** 9 mg daily.

**Pregnant adolescents ages 14 to 18.** 12 mg daily.

**Breastfeeding adolescents ages 14 to 18.** 13 mg daily.

**Children ages 9 to 13.** 8 mg daily.

**Children ages 4 to 8.** 5 mg daily.

**Children ages 1 to 3.** 3 mg daily.

**Infants ages 7 to 13 months.** 3 mg daily.

**Newborns to 6 months.** 2 mg daily.

### **I.V. INFUSION**

**Adults and children.** 2.5 to 4 mg daily added to total parenteral nutrition (TPN) solution. *Maximum:* 12 mg daily.

**Children from birth to age 5.** 100 mcg/kg daily added to TPN solution.

**Premature infants weighing up to 3 kg.** 300 mcg/kg daily added to TPN solution.

➤ *To treat zinc deficiency*

## **CAPSULES, E.R. TABLETS, LOZENGES, TABLETS**

**Adults and children.** Dosage individualized based on severity of deficiency.

## **I.V. INFUSION**

**Adults and adolescents.** 2.5 to 4 mg daily added to TPN solution. *Maximum:* 12 mg daily.

**Children from birth to age 5.** 100 mcg/kg daily added to TPN solution.

**Premature infants weighing up to 3 kg.** 300 mcg/kg daily added to TPN solution.

➤ *As adjunct maintenance therapy for patients previously treated for Wilson's disease*

## **CAPSULES**

**Adults.** 50 mg three times a day.

**Pregnant women.** 25 mg three times a day, increased to 50 mg three times a day if drug effectiveness decreases.

**Children age 10 and over.** 25 mg three times a day, increased to 50 mg three times a day if drug effectiveness decreases.

## **Mechanism of Action**

Needed for proper function of more than 200 metalloenzymes (those with tightly bound zinc atoms as an integral part of their structure), including alcohol

dehydrogenase, alkaline phosphatase, carbonic anhydrase, carboxypeptidase A, and RNA polymerase. Zinc also helps maintain cell membrane, nucleic acid, and protein structure and is essential for certain physiologic functions, including cell growth and division, dark adaptation and night vision, host immunity, sexual maturation and reproduction, taste acuity, and wound healing. This mineral also provides cellular antioxidant protection by scavenging free radicals.

In addition, zinc acetate interferes with intestinal absorption of copper and produces a protein that binds with copper, preventing its transfer to blood. Bound copper is then excreted in stools, thus decreasing copper toxicity in Wilson's disease.

## **Contraindications**

Hypersensitivity to zinc or its components

## **Interactions**

### **DRUGS**

*copper supplements:* Impaired copper absorption (with large doses of zinc)

*oral iron supplements, oral phosphate salts, phosphorus-containing drugs:* Decreased zinc absorption

*quinolones, tetracyclines:* Decreased absorption and possibly decreased effectiveness of these antibiotics

*thiazide diuretics:* Increased urinary excretion of zinc

*zinc-containing preparations:* Increased blood zinc level

### **FOODS**

*fiber- or phylate-containing foods (such as bran, cereals, whole-grain breads), phosphorus-containing foods*

*(including milk, poultry): Decreased zinc absorption*

## **Adverse Reactions**

**CNS:** Neurologic deterioration

**GI:** Elevated alkaline phosphate, amylase, and lipase; gastric irritation; nausea; vomiting

## **Nursing Considerations**

**WARNING** Don't give I.V. zinc preparations that contain benzyl alcohol to neonates or premature infants because this preservative may cause a fatal toxic syndrome characterized by metabolic acidosis and CNS, circulatory, renal and respiratory function impairment.

- Give oral zinc supplements 1 hour before or 2 to 3 hours after meals; at least 2 hours after giving oral iron supplements (to prevent decreased zinc absorption) or copper supplements (to prevent decreased copper absorption); and at least 6 hours before or 2 hours after administering quinolone or tetracycline antibiotics (to prevent decreased absorption of these drugs).
- Monitor patient receiving long-term zinc therapy for sideroblastic anemia, which may result from zinc-induced copper deficiency and is characterized by anemia, bone marrow problems, granulocytopenia, leukopenia, and neutropenia. Be aware that these effects are reversible after zinc is discontinued.
- Monitor patient with preexisting copper deficiency for exacerbation of this condition; zinc can decrease serum copper level.
- Monitor blood alkaline phosphatase level monthly, as ordered; it may increase.
- Be aware that zinc chloride contains aluminum, which may accumulate to the point of toxicity if patient's kidney function is impaired. Assess kidney function regularly.

## **PATIENT TEACHING**

- Explain the need for a zinc supplement.
- Instruct patient to take zinc on an empty stomach, at least 1 hour before or 2 hours after meals. Caution her not to take zinc within 2 hours of iron or copper supplements or phosphorus-containing drugs.
- Instruct patient to let zinc lozenge dissolve in mouth slowly and completely and not to swallow it whole or chew it. Advise her not to take zinc lozenges more often than directed.

## ziprasidone hydrochloride

**Geodon, Zeldox (CAN)**

## ziprasidone mesylate

**Geodon for Injection**

### Class and Category

*Pharmacologic class:* Benzisoxazole

*Therapeutic class:* Antipsychotic

*Pregnancy category:* C

### Indications and Dosages

➤ *To treat schizophrenia*

#### CAPSULES

**Adults.** *Initial:* 20 mg twice daily with food. Dosage increased as indicated every 2 or more days. *Usual:* 20 to 80 mg twice daily with food. *Maximum:* 80 mg twice daily.

- *To treat acute agitation in schizophrenic patients*

## **I.M. INJECTION**

**Adults.** *Initial:* 10 to 20 mg. 10 mg dose may be given every 2 hr up to maximum dose; 20 mg dose may be given every 4 hr up to maximum dose. *Maximum:* 40 mg daily for no longer than 3 consecutive days.

- *To treat acute manic or mixed episodes of bipolar disorder*

## **CAPSULES**

**Adults.** *Initial:* 40 mg twice daily. with food on day 1; then increased to 60 or 80 mg on day 2 with food with further adjustments as needed.

- *As adjunct to lithium or valproate for maintenance treatment of bipolar I disorder*

## **CAPSULES**

**Adults.** Same dose patient was initially stabilized on that falls within 40 to 80 mg twice daily and taken with food.

## **Mechanism of Action**

Selectively blocks dopamine and serotonin receptors in the mesocortical tract of the CNS, thereby suppressing psychotic symptoms.

## **Incompatibilities**

Don't mix injection form with drugs or solvents other than sterile water for injection.

## Contraindications

Concurrent use of other drugs that prolong QT interval, history of arrhythmia or prolonged QT interval, hypersensitivity to ziprasidone or its components, recent acute MI, uncompensated heart failure

## Interactions

### DRUGS

*antihypertensives*: Additive antihypertensive effects

*carbamazepine*: Possibly decreased blood ziprasidone level

*CNS depressants*: Increased CNS depression

*dopamine agonists, levodopa*: Decreased therapeutic effects of these drugs

*drugs that prolong QT interval (including dofetilide, pimozide, quinidine, sotalol, sparfloxacin, and thioridazine)*: Increased risk of prolonged QT interval, torsades de pointes, and sudden death

*ketconazole*: Possibly increased blood ziprasidone level

### FOODS

*all foods*: Increased ziprasidone absorption

## Adverse Reactions

**CNS**: Agitation, akathisia, amnesia, anxiety, asthenia, **CVA**, depression, dizziness, dystonia, extrapyramidal reactions, headache, hypertonia, hypomania, insomnia, mania, **neuroleptic malignant syndrome**, paresthesia, personality or speech disorder, **serotonin syndrome**, somnolence, syncope, **suicidal ideation**, tardive dyskinesia, tremor

**CV:** **Bradycardia**, chest pain, hypercholesterolemia, hypertension, orthostatic hypotension, **prolonged QT interval**, tachycardia, thrombophlebitis, vasodilation  
**EENT:** Abnormal vision, dry mouth, increased salivation, rhinitis, tongue swelling  
**ENDO:** Dysmenorrhea, hyperglycemia, hyperprolactinemia  
**GI:** Abdominal pain, anorexia, constipation, diarrhea, dysphagia, indigestion, nausea, **rectal bleeding**, vomiting  
**GU:** Priapism, urinary incontinence  
**HEME:** **Agranulocytosis**, **leukopenia**, **neutropenia**  
**MS:** Arthralgia, back pain, dysarthria, myalgia  
**RESP:** Cough, **pulmonary embolism**, upper respiratory tract infection  
**SKIN:** Allergic dermatitis, diaphoresis, **exfoliative dermatitis**, furunculosis, rash, **Stevens-Johnson syndrome**, urticaria  
**Other:** Accidental injury, **angioedema**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, flu-like symptoms, injection-site pain, weight gain

## Nursing Considerations

**WARNING** Know that ziprasidone shouldn't be used to treat elderly patients with dementia-related psychosis because drug increases the risk of death in these patients.

- Protect ziprasidone vials from light. Reconstitute by adding 1.2 ml sterile water for injection to vial and shaking vigorously until drug is dissolved. Each ml of reconstituted solution contains 20 mg ziprasidone. Discard any unused portion.
- Give parenteral form only by I.M. route and administer cautiously to patients with renal dysfunction.
- Reconstituted drug may be stored 24 hours protected from light or up to 7 days if refrigerated and protected from light.

**WARNING** Assess cardiac rhythm in patients with hypokalemia or hypomagnesemia. Dizziness, palpitations, and syncope may indicate life-threatening torsades de pointes. Be prepared to stop ziprasidone if QT interval is greater than 500 msec.

- Monitor patient, especially elderly women, for involuntary movements, which may become irreversible tardive dyskinesia. If symptoms develop, notify prescriber immediately and be prepared to stop drug.
- Immediately report evidence of neuroleptic malignant syndrome, a rare but potentially fatal adverse reaction including acute renal failure, altered mental status, arrhythmia, blood pressure changes, diaphoresis, hyperpyrexia, irregular pulse, muscle rigidity, myoglobinuria (rhabdomyolysis), and tachycardia.
- Monitor patient's blood glucose and lipid levels routinely, as ordered, because drug increases risk of hypercholesterolemia and hyperglycemia.
- Monitor patient's CBC, as ordered, because serious adverse hematologic reactions may occur, such as agranulocytosis, leukopenia, and neutropenia. Monitor more frequently during first few months of therapy if patient has a history of drug-induced leukopenia, neutropenia, or significantly low WBC count. If abnormalities occur during ziprasidone therapy, watch for fever and other evidence of infection, notify prescriber, and expect to discontinue drug if severe.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.
- Know that long-standing hyperprolactinemia caused by ziprasidone therapy may cause decreased bone density if associated with hypogonadism.
- Institute fall precautions.

## **PATIENT TEACHING**

- Instruct patient to take ziprasidone with food to increase absorption.
- Advise patient to avoid hazardous activities until CNS effects are known. Review fall precautions with patient and family or caregiver.
- Tell family to monitor patient closely for suicidal tendencies; patients with bipolar disorder or psychotic illness are at greater risk.

- Urge patient to rise slowly from lying or seated position to minimize orthostatic hypotension.
- Urge patient to notify prescriber immediately if he develops persistent, severe, sudden-onset, or unusual adverse reactions, especially a fever, rash, or swollen lymph nodes. If present, tell him to stop taking ziprasidone and seek urgent medical care.

## zoledronic acid

### Reclast, Zometa

## Class and Category

*Pharmacologic class:* Bisphosphonate

*Therapeutic class:* Antiosteoporotic

*Pregnancy category:* D

## Indications and Dosages

➤ *To treat hypercalcemia caused by cancer*

### I.V. INFUSION (ZOMETA)

**Adults.** 4 mg infused over at least 15 min. After 7 days, retreatment with 4 mg if serum calcium level doesn't remain at or return to normal. *Maximum:* 4 mg/dose.

➤ *As adjunct treatment for patients with multiple myeloma or bony metastasis who are receiving standard antineoplastic therapy and have a creatinine clearance above 60 ml/min*

### I.V. INFUSION (ZOMETA)

**Adults.** 4 mg infused over at least 15 min every 3 to 4 wk.

**DOSAGE ADJUSTMENT** If patient's creatinine clearance is 50 to 60 ml/min dosage decreased to 3.5 mg; if it's 40 to 49 ml/min dosage decreased to 3.3 mg; and if it's 30 to 39 ml/min/dosage decreased to 3 mg.

- *To treat postmenopausal osteoporosis in women; to treat osteoporosis in men; to treat and prevent glucocorticoid-induced osteoporosis in patients receiving daily prednisone doses of 7.5 mg or greater for at least 12 months*

## **I.V. INFUSION (RECLAST)**

**Adults.** 5 mg infused over at least 15 min once yearly.

- *To treat Paget's disease of the bone*

## **I.V. INFUSION (RECLAST)**

**Adults.** 5 mg infused over at least 15 min followed by 1,500 mg elemental calcium daily in divided doses and 800 international units of vitamin D daily for 2 wk.

- *To prevent osteoporosis in postmenopausal women*

## **I.V. INFUSION (RECLAST)**

**Adults.** 5 mg infused over at least 15 min every 2 yr.

## **Mechanism of Action**

Inhibits resorption of mineralized bone and cartilage by osteoclasts and induces osteoclast breakdown. In cancer-related hypercalcemia, hyperactive osteoclasts cause bone resorption and release of calcium into blood, which causes polyuria, GI disruption, progressive dehydration, and decreasing GFR. This, in turn, increases renal calcium

resorption and worsens hypercalcemia. Zoledronic acid interrupts this process.

## Incompatibilities

Don't mix zoledronic acid with calcium-containing I.V. solutions, such as lactated Ringer's solution.

## Contraindications

Acute renal impairment, creatinine clearance less than 35 ml/min; hypersensitivity to zoledronic acid, other bisphosphonates, or their components

## Interactions

### DRUGS

*aminoglycosides, calcitonin*: Possibly additive serum calcium-lowering effect  
*angiogenesis inhibitors, chemotherapy, corticosteroids*: Increased risk of osteonecrosis of the jaw  
*loop diuretics, such as furosemide*: Possibly increased risk of hypocalcemia  
*nephrotoxic drugs, NSAIDs*: Increased risk of nephrotoxicity

## Adverse Reactions

**CNS**: Anxiety, asthenia, chills, confusion, depression, dizziness, fatigue, fever, headache, hyperesthesia, hypoesthesia, insomnia, malaise, paresthesia, tremor, vertigo, weakness

**CV**: **Atrial fibrillation**, **bradycardia**, chest pain, hypertension, **hypotension**, peripheral edema

**EENT:** Blurred vision, conjunctivitis, dry mouth, episcleritis, iritis, orbital edema or inflammation, osteonecrosis of external auditory canal, scleritis, sore throat, stomatitis, taste disturbance, uveitis

**GI:** Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, nausea, vomiting

**GU:** **Acquired Fanconi syndrome**, elevated serum creatinine level, hematuria, proteinuria, **renal insufficiency or failure**, UTI

**HEME:** Anemia, **neutropenia**, **thrombocytopenia**

**MS:** Arthralgia; atypical subtrochanteric and diaphyseal femoral fractures; incapacitating bone, joint, or muscle pain; muscle cramps or spasms; myalgia; osteonecrosis of the jaw, femur, or hip

**RESP:** **Bronchospasm**, cough, dyspnea, **exacerbation of asthma**, **interstitial lung disease**, upper respiratory tract infection

**SKIN:** Alopecia, dermatitis, diaphoresis, flushing, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Aggravated malignant neoplasm**, **anaphylaxis**, **angioedema**, flu-like illness, **hypersensitivity reactions**, **hyperkalemia**, **hypernatremia**, **hypocalcemia**, **hypomagnesemia**, **hypophosphatemia**, infusion-site redness and swelling, weight gain

## Nursing Considerations

- Be aware that zoledronic acid isn't indicated for hypercalcemia from hyperparathyroidism or other nontumor conditions.
- Verify pregnancy status of women of childbearing age before zoledronic acid therapy is initiated, because drug can cause fetal harm.
- Use cautiously in patients with aspirin sensitivity because biphosphonates such as zoledronic acid have caused bronchoconstriction in these patients.

- Make sure patient has had a dental checkup before zoledronic acid starts, especially if patient has cancer; is receiving chemotherapy, head or neck radiation, or a corticosteroid; or has poor oral hygiene because risk of jaw osteonecrosis is increased in these patients, and invasive dental procedures during zoledronic acid therapy may worsen osteonecrosis.
- Expect to aggressively hydrate hypercalcemic patient with I.V. normal saline solution before and during zoledronic acid therapy, as prescribed, to achieve and maintain urine output of about 2 L daily.

**WARNING** Monitor fluid intake and output often during hydration, and assess patient, especially one with heart failure, for evidence of life-threatening overhydration.

- Expect to give acetaminophen, if not contraindicated, before zoledronic acid to reduce adverse reactions, such as fever, flu-like symptoms, headache, and myalgia. Joint swelling may also occur. These reactions usually occur within first 3 days after zoledronic acid administration and resolve within 3 days (although resolution may take up to 14 days for some patients).
- Be aware that Reclast doesn't require reconstitution.
- Know that hypocalcemia and mineral metabolism disorders must be treated before zoledronic acid therapy begins.
- Reconstitute Zometa by adding 5 ml of sterile water for injection to drug vial to yield solution that contains 4 mg of zoledronic acid. Make sure drug is completely dissolved before withdrawing prescribed dose. Further dilute in 100 ml normal saline solution or 5% dextrose injection, and infuse over no less than 15 minutes.
- Inspect reconstituted and diluted solution before giving drug, and discard it if particles or discoloration are present.
- Refrigerate reconstituted drug at 2° to 8° C (36° to 46° F) and discard after 24 hours.
- Give drug as a single I.V. solution in a separate I.V. line.

**WARNING** Be aware that a single dose of Zometa shouldn't exceed 4 mg, and that neither Zometa nor Reclast should be infused over less than 15 minutes; exceeding these limits may lead to significant renal function deterioration, which may progress to renal failure.

**WARNING** Assess patient's renal function, as ordered, before and during zoledronic acid therapy to detect renal deterioration. For patient with a normal serum creatinine level who develops an increase of 0.5 mg/dl within 2 weeks of receiving zoledronic acid, expect to withhold next dose until serum creatinine level is within 10% of patient's baseline value. For patient with an abnormal serum creatinine level who develops an increase of 1.0 mg/dl within 2 weeks of receiving drug, expect to withhold next dose until serum creatinine level is within 10% of baseline value.

- Monitor patient's serum calcium, magnesium, and phosphate levels, as ordered, during zoledronic acid therapy. If hypocalcemia, hypomagnesemia, or hypophosphatemia occurs, expect to give short-term supplemental therapy.
- Assess aspirin-sensitive asthma patients for worsening of respiratory symptoms during zoledronic acid therapy because other bisphosphonates have caused bronchoconstriction in these patients.
- Monitor patient for dehydration. If present, notify prescriber and expect drug to be withheld until dehydration has been corrected.
- Monitor patient for acute phase reaction (APR) that may occur within 3 days following intravenous administration of zoledronic acid. If patient develops flu-like symptoms such as arthralgias, bone pain, chills, fever, flushing, and myalgias, notify prescriber.
- Store drug at 25° C (77° F).
- Monitor patient closely for severe and occasionally incapacitating bone, joint, and/or muscle pain. If present, notify prescriber and expect to provide supportive care, as ordered, for pain relief.

## **PATIENT TEACHING**

- Teach patient the importance of eating a nutritious diet, including adequate amounts of calcium and vitamin D. Tell patients with multiple myeloma and bone metastasis of solid tumors to check with prescriber about the need for an oral calcium supplement containing 500 mg of calcium and a multivitamin containing 400 international units of vitamin D.

- Instruct patient to drink at least two glasses of fluid within a few hours before receiving zoledronic acid intravenously.
- Advise patient to alert prescriber about bone, joint, or muscle pain or new or worsening groin, hip, or thigh pain.
- Instruct patient on proper oral hygiene and on need to notify prescriber before undergoing invasive dental procedures.
- Tell patient to notify prescriber if he notices blood or other changes in his urine or a change in amount of urine voided or frequency of voiding pattern. Stress importance of compliance in having regular blood tests that have been ordered to check his kidney function.
- Advise women of childbearing age to use effective contraception during and after zoledronic acid therapy and to notify prescriber immediately if they are or could be pregnant, because drug will have to be stopped. Alert female patients that drug may also impair fertility. Also inform these patients that breastfeeding is also not recommended during zoledronic acid therapy.
- Inform patient not to take other bisphosphonates concurrently, including Reclast if they are prescribed Zometa or Zometa if they are prescribed Reclast.

## zolmitriptan

### Zomig, Zomig ZMT

## Class and Category

*Pharmacologic class:* Selective 5-hydroxytryptamine agonist

*Therapeutic class:* Antimigraine

*Pregnancy category:* C

## Indications and Dosages

- *To treat acute migraine headache with or without aura*

## ORAL DISINTEGRATING TABLETS, TABLETS

**Adults.** *Initial:* 1.25 or 2.5 mg, repeated in 2 hr as needed. *Maximum:* 5 mg as a single dose, 10 mg in 24 hr, or 3 headaches/mo.

## NASAL SPRAY

**Adults and children age 12 and over.** *Initial:* 2.5 mg repeated in 2 hr as needed. Dosage increased to 5 mg/episode, as needed. *Maximum:* 5 mg as single dose; 10 mg/24 hr; or 4 headaches/mo.

**DOSAGE ADJUSTMENT** For patient with moderate to severe hepatic impairment, initial oral dosage using tablet form should not be higher than 1.25 mg and maximum dose should not exceed 5 mg in 24 hr. Nasal spray or oral disintegrating tablets are not recommended for these patients. For patient receiving cimetidine concurrently, single dosage should not exceed 2.5 mg and the maximum dosage should not exceed 5 mg in a 24-hr period.

## Mechanism of Action

Constricts dilated and inflamed cranial blood vessels in the carotid circulation and inhibits production of proinflammatory neuropeptides by binding to receptors on intracranial blood vessels and sensory nerves in the trigeminal-vascular system to stimulate negative feedback, which halts the release of serotonin.

## Contraindications

Basilar or hemiplegic migraine, cardiovascular disease, concurrent use of ergotamine-containing drugs, hypersensitivity to zolmitriptan or its components, ischemic heart disease, peripheral vascular disease, Prinzmetal's

angina, symptomatic Wolff-Parkinson-White syndrome or other accessory pathway conduction disorder, use of another 5-hydroxytryptamine agonist within past 24 hours, use of an MAO inhibitor within 14 days

## Interactions

### DRUGS

*acetaminophen*: Delayed peak effect of acetaminophen (by 1 hour)

*cimetidine*: Prolonged zolmitriptan half-life

*ergot alkaloids*: Prolonged vasoconstriction effects

*fluoxetine, fluvoxamine, paroxetine, sertraline*:

Hyperreflexia, lack of coordination, and weakness

*MAO inhibitors*: Increased zolmitriptan effects

*naratriptan, rizatriptan, sumatriptan*: Prolonged zolmitriptan effects

*norepinephrine and serotonin reuptake inhibitors*:

Increased risk of developing serotonin syndrome

*oral contraceptives, propranolol*: Increased blood zolmitriptan level

## Adverse Reactions

**CNS**: Asthenia, dizziness, hyperesthesia, paresthesia, somnolence, vertigo

**CV**: Angina, **coronary artery vasospasm**, hypertension,

**MI**, palpitations, transient myocardial ischemia,

**ventricular fibrillation or tachycardia**

**EENT**: Dry mouth, vision disturbance

**GI**: Abdominal pain, **bloody diarrhea**, dysphagia, **GI or splenic infarction**, indigestion, **ischemic colitis**, nausea, vomiting

**MS:** Myalgia; myasthenia; pain, pressure, or tightness in jaw, neck, or throat

**SKIN:** Diaphoresis, flushing

**Other:** **Anaphylaxis, angioedema**

## Nursing Considerations

**WARNING** Monitor patient for signs and symptoms of vasoconstriction, which may lead to colonic and vascular ischemia with abdominal pain and bloody diarrhea, especially if patient has ischemic bowel disease or peripheral vascular disease (including Raynaud's phenomenon).

- Monitor elderly patients and those with hepatic impairment for increased blood pressure, and notify prescriber immediately if it occurs.
- Monitor patient closely for signs and symptoms of angina. If patient develops chest pain, notify prescriber.

**WARNING** Monitor patient closely for signs and symptoms of serotonin syndrome, which may include agitation, coma, diarrhea, hallucinations, hyperreflexia, hyperthermia, incoordination, labile blood pressure, nausea, tachycardia, and vomiting. Notify prescriber immediately because serotonin syndrome may be life-threatening. Be prepared to provide supportive care and discontinue zolmitriptan.

## PATIENT TEACHING

- Instruct patient to take zolmitriptan exactly as prescribed. Tell her also not to take more than 10 mg in any 24-hour period, nor should she take drug for more than recommended number of times per month because overuse of drug may lead to exacerbation of headache. Tell her to be alert for migraine-like daily headaches developing or marked increase in frequency of migraine headaches that signals overuse may be occurring.

Tell her to notify prescriber, as drug may no longer be as effective and drug withdrawal may be needed.

- Advise patient not to remove disintegrating tablet from blister pack until just before taking the tablet. Instruct her to peel open pack, let tablet dissolve on her tongue, and then swallow. Remind her not to break orally disintegrating tablet. However, if she is prescribed the regular 2.5-mg tablet form, she may break it in half, if needed for a 1.25-mg dose.
- Urge patient to notify prescriber about severe or unusual adverse reactions.
- Caution patient using nasal spray to avoid spraying drug into her eyes.
- Instruct patient not to take zolmitriptan within 24 hours of other drugs in the same class.
- Tell patient to inform all prescribers of zolmitriptan therapy because serious drug interactions may occur.
- Advise women of childbearing age to notify prescriber if pregnancy occurs, because of increased risk of preeclampsia during pregnancy. Also tell mothers wishing to breastfeed to discuss this with prescriber before doing so.

## zolpidem tartrate

**Ambien, Ambien CR, Edluar,  
Intermezzo, Zolpimist**

### **Class, Category, and Schedule**

*Pharmacologic class:* Imidazopyridine

*Therapeutic class:* Hypnotic

*Pregnancy category:* C

*Controlled substance schedule:* IV

### **Indications and Dosages**

- *To provide short-term treatment of insomnia*

## **ORAL SPRAY, S.L. TABLETS, TABLETS**

**Adult men.** 5 to 10 mg at bedtime for 7 to 10 days.

*Maximum:* 10 mg daily.

**Adult women.** 5 mg at bedtime for 7 to 10 days.

*Maximum:* 5 mg daily.

***DOSAGE ADJUSTMENT*** For elderly men or debilitated male patients and men with mild to moderate hepatic impairment, dosage possibly reduced to 5 mg at bedtime, with a maximum of 5 mg daily for nursing facility residents.

## **E.R. TABLETS**

**Adult men.** 6.25 or 12.5 mg immediately before bedtime.

**Adult women.** 6.25 mg immediately before bedtime.

***DOSAGE ADJUSTMENT*** For elderly or debilitated patients and those with mild to moderate hepatic impairment, dosage reduced to 6.25 mg immediately before bedtime.

- *To treat insomnia when a middle-of-the-night awakening occurs and patient cannot get back to sleep and has more than 4 hours of sleep remaining before planned time of waking.*

## **S.L. TABLETS (INTERMEZZO)**

**Adult women.** 1.75 mg once nightly, as needed.

**Adult men.** 3.5 mg once nightly, as needed.

***DOSAGE ADJUSTMENT*** For elderly men or male patients with hepatic impairment or who take concomitant CNS depressants, dosage reduced to 1.75 mg once nightly, as needed.

## **Mechanism of Action**

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters. By binding to specific benzodiazepine receptors in the limbic and cortical areas of the CNS, zolpidem increases GABA's inhibitory effects, blocks cortical and limbic arousal, and preserves deep sleep (stages 3 and 4).

## Contraindications

Hypersensitivity to zolpidem or its components, ritonavir therapy, severe hepatic impairment

## Interactions

### DRUGS

*barbiturates, chlorpromazine, general anesthetics, opioid agonists, other CNS depressants, phenothiazines, tramadol, tricyclic antidepressants:* Possibly increased CNS depression and reduced psychomotor function

*bupropion:* Increased blood zolpidem level, possibly visual hallucinations, loss of alertness

*CYP3A4 inducers such as rifampin, St. John's wort:*  
Decreased effectiveness of zolpidem

*CYP3A4 inhibitors such as ketoconazole:* Increased risk of zolpidem-induced adverse reactions

*desipramine, imipramine:* Increased risk of visual hallucinations and reduced alertness

*flumazenil:* Antagonized sedative effect

*haloperidol:* Increased CNS depression

*nevirapine:* Decreased blood zolpidem level

*selective serotonin-reuptake inhibitors:* Increased risk of delusions, disorientation, and hallucinations

### FOOD

*all foods:* Increased time to peak blood zolpidem level, decreased effects of zolpidem

## ACTIVITIES

*alcohol use:* Increased CNS depression

## Adverse Reactions

**CNS:** Abnormal thinking, aggressiveness, amnesia, asthenia, ataxia, behavioral changes, complex behaviors (such as sleep driving), confusion, decreased level of consciousness or inhibition, dizziness, drowsiness, euphoria, hallucinations, headache, insomnia, lethargy, paradoxical CNS stimulation (including agitation, euphoria, hallucinations, hyperactivity, and nightmares), **suicidal ideation**, vertigo, worsening of depression

**EENT:** Application site reactions from sublingual dose form (blisters, mucosal inflammation, oral ulcers), blurred vision, diplopia, **throat tightness**, visual abnormality

**GI:** Constipation, diarrhea, elevated liver enzymes, **hepatic injury**, hiccups, indigestion, jaundice, nausea, vomiting

**GU:** UTI

**MS:** Arthralgia, myalgia

**RESP:** Dyspnea, **respiratory depression**, upper or lower respiratory infection

**Other:** **Anaphylaxis**, **angioedema**, withdrawal symptoms

## Nursing Considerations

- Use zolpidem cautiously in patients with additional disorders because it isn't known if zolpidem therapy might aggravate these conditions, especially conditions with respiratory impairment.
- Administer zolpidem just before patient's bedtime because drug has a rapid onset of action.

- Expect patient to receive no more than a 1-month supply of zolpidem for outpatient therapy.

**WARNING** Keep in mind if zolpidem is withdrawn abruptly (especially after prolonged therapy), monitor patient for withdrawal symptoms, such as abdominal cramps or discomfort, fatigue, flushing, inconsolable crying, light-headedness, nausea, nervousness, panic attack, rebound insomnia, and vomiting.

- Expect that zolpidem will produce anticonvulsant and muscle relaxant effects at high doses.
- Know that if patient takes other CNS depressants, expect to reduce zolpidem dosage, as prescribed.
- Monitor patient closely for suicidal tendencies, particularly when therapy starts or dosage increases because depression may worsen temporarily during these times, possibly leading to suicide.

**WARNING** Monitor patient closely for hypersensitivity reactions such as dyspnea, nausea, swelling, throat tightness, or vomiting. If present, discontinue zolpidem immediately, notify prescriber, and provide supportive care.

- Monitor neonates born to mothers using zolpidem late in the third trimester of pregnancy for hypotonia, respiratory depression, and sedation.

## **PATIENT TEACHING**

- Caution patient to take drug exactly as prescribed and not to increase dosage unless directed by prescriber.
- Advise patient taking extended-release form to swallow tablet whole and not to break, chew, or crush it.
- Instruct patient to take zolpidem (except for Intermezzo brand of sublingual tablets) immediately before going to bed, on an empty stomach.

- Tell patient prescribed Intermezzo brand of sublingual tablets to keep tablets at bedside and take only once if awoken during the night but has more than 4 hours of sleep time remaining. Instruct patient to place tablet under his tongue and allow it to dissolve completely before swallowing. Tell him never to swallow the sublingual tablet whole.
- Advise patient to notify prescriber immediately about abdominal cramps or discomfort, fatigue, flushing, inconsolable crying, light-headedness, nausea, nervousness, panic attack, and vomiting.
- Instruct patient to stop taking zolpidem and seek emergency care if she has abnormal swelling, nausea, throat tightness, trouble breathing, or vomiting.
- Advise patient that zolpidem may produce abnormal behaviors during sleep, such as driving a car, eating, talking on the phone, or having sex without any recall of the event. If patient's family notices any such behavior or if patient sees evidence of such behavior upon awakening, prescriber should be notified.
- Tell patient that drug may cause drowsiness or decreased level of consciousness and even next-morning impairment from zolpidem use despite feeling fully awake. Advise patient to get a good night's sleep of at least 7 or 8 hours to help minimize this adverse effect. Tell her to take precautions against falling and not to perform any hazardous activity such as driving, especially after taking the drug and during the morning hours.
- Tell family or caregiver to observe patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Advise mothers breastfeeding during zolpidem therapy to monitor the infant for excess sedation, hypotonia, and slower-than-normal breathing, because drug passes through into breast milk. Encourage mother instead to interrupt breastfeeding, if possible, and pump and then discard breast milk during zolpidem therapy and for 23 hours after drug administration in order to minimize drug exposure of the breastfed infant.

## zonisamide

### Zonegran

# Class and Category

*Pharmacologic class:* Sulfonamide

*Therapeutic class:* Anticonvulsant

*Pregnancy category:* C

# Indications and Dosages

► *As adjunct to treat partial seizures*

## CAPSULES

**Adults.** *Initial:* 100 mg daily. Dosage increased by 100 mg daily every 2 wk, as needed. *Usual:* 200 to 400 mg daily.

*Maximum:* 400 mg daily.

# Mechanism of Action

May stop seizures and suppress their foci by blocking sodium channels and reducing voltage-dependent, inward currents from calcium channels. This action stabilizes neuronal membranes and suppresses synchronized neuronal hyperactivity.

# Contraindications

Hypersensitivity to zonisamide, other sulfonamides, or their components

# Interactions

## DRUGS

*carbamazepine, phenobarbital, phenytoin, valproate:*

Possibly decreased blood zonisamide level

*CNS depressants:* Additive CNS depressant effects

## **FOODS**

*grapefruit juice:* Possibly decreased metabolism of zonisamide

## **Adverse Reactions**

**CNS:** Abnormal gait, agitation, anxiety, asthenia, ataxia, confusion, depression, difficulty concentrating, dizziness, fatigue, headache, incoordination, insomnia, irritability, memory loss, nervousness, paresthesia, schizophrenia, **seizures**, somnolence, speech abnormalities, **suicidal ideation**, tremor

**CV:** Chest pain

**EENT:** Amblyopia, diplopia, dry mouth, nystagmus, pharyngitis, rhinitis, taste alteration, tinnitus

**GI:** Abdominal pain, **acute pancreatitis**, anorexia, constipation, diarrhea, dyspepsia, nausea, vomiting

**GU:** Renal calculi

**HEME:** Anemia, **leukopenia**, **thrombocytopenia**

**MS:** Elevated creatine phosphokinase levels, **rhabdomyolysis**

**RESP:** Increased cough

**SKIN:** Ecchymosis, pruritus, rash

**Other:** **Angioedema**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, flu-like symptoms, **metabolic acidosis**, weight loss

## **Nursing Considerations**

- Obtain a serum bicarbonate level before starting zonisamide and then periodically during therapy, as prescribed because drug may cause

metabolic acidosis, especially in patients with predisposing conditions or therapies or who are younger in age.

**WARNING** Monitor results of patient's CBC and other laboratory tests for signs of blood dyscrasias because zonisamide is a sulfonamide and can be absorbed systemically. Systemic absorption may result in life-threatening reactions, including agranulocytosis, aplastic anemia, and other blood dyscrasias; fulminant hepatic necrosis; Stevens-Johnson syndrome; and toxic epidermal necrolysis.

- Be aware that patients receiving doses of 300 mg daily or more are at increased risk for adverse CNS reactions, including decreased concentration, drowsiness, fatigue, and impaired speech.
- Monitor BUN and serum creatinine levels for signs of abnormally decreased glomerular filtration rate (GFR). Expect some decrease in GFR during first 4 weeks of treatment and return to baseline within 2 to 3 weeks after drug is discontinued.
- Monitor patient for signs and symptoms of renal calculi.
- Be aware that zonisamide shouldn't be discontinued abruptly because doing so may increase frequency of seizures.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

## **PATIENT TEACHING**

- Inform patient that zonisamide is usually prescribed with other anticonvulsants and that she should continue to take all drugs as prescribed.
- Instruct patient to swallow zonisamide capsules whole and not to break them open or chew them.
- Inform patient that prescriber may have to adjust zonisamide dosage over several weeks or months before stable dose is achieved.
- Advise patient to use caution when driving or performing other activities that are hazardous or require mental alertness because zonisamide

commonly causes decreased concentration, dizziness, and somnolence, particularly during first month of therapy.

- Advise patient to wear a medical identification bracelet or necklace or carry medical identification with information about her seizure disorder.
- Encourage patient to drink six to eight glasses of water each day to prevent kidney stones, unless contraindicated.
- Advise patient to rise slowly from a lying or seated position to reduce the risk of dizziness.
- Urge caregivers to watch closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns immediately to prescriber.
- Encourage woman who becomes pregnant while taking zonisamide to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy.
- Instruct patient to notify prescriber immediately if seizures worsen, signs of blood abnormalities (fever, sore throat, oral ulcers, easy bruising) are present, signs of kidney stones occur (abdominal pain, blood in urine, sudden back pain), or a skin rash develops. She should also report signs and symptoms such as fast breathing, fatigue, irregular heart beat, loss of appetite, or palpitations.

# Safety Guidelines for Opioid Use

Pain relief has been a long-standing goal in health care for patients with pain. Patients may experience short-term pain as a result of an illness, injury, or medical or surgical procedure. Others experience chronic or persistent pain, defined as pain that lasts longer than 3 months or beyond normal tissue healing, which can drastically alter quality of life.

Opioids are powerful pain-reducing drugs, and their efficacy has made them increasingly popular for both short- and long-term pain management. However, opioids are also addictive, especially when used inappropriately. This has led to their abuse and misuse in society, along with a sharp increase in recent years of opioid-related overdoses and deaths.

In an effort to address the opioid crisis in the United States, the Food and Drug Administration (FDA) has formulated and implemented a plan called the *FDA Opioids Action Plan*. This plan details seven measures the FDA is using to combat this problem and includes:

- Expanding the use of advisory committees to approve any new drug application for an opioid that does not have abuse-deterrent properties, as well as seeking expert advice on opioid labeling regarding use by children.
- Providing clearer information to prescribers of opioids by making certain changes to immediate-release opioid labeling similar to those issued in 2013 for extended-release or long-acting opioid analgesics.
- Requiring drug companies to address issues of abuse and misuse associated with long-term use of their opioid drug products, provide predictors of opioid addiction, and explore other important issues related to opioid addiction through adherence to postmarketing requirements.
- Increasing training for prescribers on pain management and safe prescription use of opioid drugs.
- Encouraging the development of abuse-deterrent formulations, especially generic opioid formulations.
- Making naloxone more accessible to treat opioid overdose while at the same time encouraging drug companies to develop new classes of analgesics that would be as effective as opioids but not carry the same risks.
- Increasing the patient's understanding of the risks associated with opioids, and the risks of misuse by other persons who obtain them.

As a result of the FDA Opioids Action Plan, drug companies are now required to address several safety issues in their opioid drug labels (package inserts). Changes to individual sections of the drug label reflective of these safety issues are summarized here:

- **Boxed Warning**—Now includes warnings about addiction, abuse, and misuse; life-threatening respiratory depression; accidental ingestion; neonatal opioid withdrawal syndrome (NOWS); and any significant drug product-specific interactions that could raise the risk of adverse reactions associated with opioid use.
- **Indications and Usage**—Modified to emphasize that opioids are to be reserved for the management of pain only if alternative treatment options such as nonopioid analgesics cannot be used or are ineffective and the pain is severe enough to require an opioid analgesic.
- **Contraindications**—Includes patients with significant respiratory depression and patients with acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment.
- **Warning and Precautions**—Addresses each of the components found in the boxed warning as well as risks associated with concurrently administered central nervous system depressants; life-threatening respiratory depression in patients with chronic pulmonary disease, in the elderly or patients who are cachectic or debilitated; and the potential development of adrenal insufficiency with opioid use.
- **Adverse Reactions**—Lists all the serious adverse reactions addressed in the “Warnings and Precautions” section of the drug label as well as adding adrenal insufficiency and serotonin syndrome to the postmarketing section.
- **Drug Interactions**—Includes any significant drug-specific interactions that would increase the opioid effect as well as interactions between opioids and central nervous system depressants, including alcohol and between opioids and serotonergic drugs.
- **Specific Populations**—Additional information included regarding NOWS and potential for neonatal respiratory depression during delivery or with breastfeeding; potential risk for infertility with chronic use; and increased risk for respiratory depression in the elderly.
- **Drug Abuse and Dependence**—Details information about opioid abuse and dependence.
- **Overdosage**—Adds or modifies information to address seriousness and current treatment of opioid overdose.
- **Patient Counseling**—Includes information to be given to the patient on addiction, abuse, and misuse of opioids; risk of life-threatening respiratory

depression or accidental ingestion; interactions with alcohol and other CNS depressants; potential for adrenal insufficiency and serotonin syndrome and what to report; potential for development of NOWS and embryo-fetal toxicity during pregnancy, respiratory depression in infants during delivery and with breastfeeding; how to dispose of the unused opioid; and the addition of a medication guide.

In addition, the Centers for Disease Control (CDC) has also released recommendations for use of opioids in treating chronic pain. These recommendations exclude patients who are in active cancer treatment, palliative care, or end-of-life care.

The CDC recommends that opioids not be used as first-line therapy in the treatment of chronic pain. Instead, nonpharmacologic therapies such as cognitive behavioral therapy or exercise, or nonopioid pharmacologic therapies such as NSAIDs, should be tried first. If opioids are prescribed, the CDC recommends that they be combined with nonpharmacologic or nonopioid pharmacologic therapy to provide greater benefits and lower opioid dosage requirements.

When opioids are used, the lowest possible effective dosage should be prescribed and therapy should start with immediate-release opioids rather than extended-release or long-acting opioids. In addition, the quantity prescribed should not go beyond the expected need for pain relief.

Closer follow-up is also recommended, with regular monitoring of patients to determine effectiveness of the prescribed pain measures. It is especially important to ascertain that the opioid is not causing harm. If benefits do not outweigh harm, it is recommended that the opioid dosage be reduced and then discontinued, if needed.

It is very important that the patient's response to pain relief measures be accurately measured and assessed. Only then can the goal to provide effective pain relief without causing the patient harm be achieved. Although opioid therapy has its place in pain management, it is important to understand that opioids are not always necessary and, if used inappropriately, can cause much harm, not only to the patient but to society in general.

---

# Parenteral Insulin Preparations

For each category of insulin, the following table lists the species; common trade names; onset, peak, and duration; and key nursing considerations.

CATEGORY, SPECIES, AND TRADE NAMES	KEY NURSING CONSIDERATIONS		
Rapid-acting insulin			
Onset: 10–20 min*	Peak: 30–90 min	Duration: 2–5 hr	
<b>Human</b> <ul style="list-style-type: none"><li>• Apidra (insulin glulisine)</li><li>• Humalog (insulin lispro)</li><li>• NovoLog (insulin aspart)</li><li>• NovoRapid (insulin aspart) (CAN)</li><li>• Fiasp (insulin aspart) (CAN)</li></ul> <b>Concentrated</b> <ul style="list-style-type: none"><li>• Humalog U-200</li></ul>		<ul style="list-style-type: none"><li>• Only mix with NPH (intermediate-type) insulin, if needed, except for Humalog U-200, which should not be mixed with any other insulin. Administer immediately after mixing.</li><li>• When mixing rapid-acting insulin with a longer-acting insulin, always draw the rapid-acting insulin into the syringe first to avoid dosage errors.</li><li>• When giving SubQ, give Humalog up to 15 minutes before a meal or immediately after a meal; give NovoLog and NovoRapid 5 to 10 minutes before a meal; give Apidra up to 15 to 20 minutes before a meal, and give Fiasp up to 2 minutes before a meal or up to 20 minutes after starting a meal. When giving rapid-acting insulin (except for Fiasp) via an insulin pump, do not dilute or mix with any other insulin, change the insulin in the reservoir at least every 48 hours (Apidra), 6 days (NovoLog, NovoRapid), and 7 days (Humalog). Change the infusion sets and insertion site at least every 3 days.</li><li>• Be aware that 1 unit of rapid-acting insulin has the same glucose-lowering ability as 1 unit of short-acting insulin.</li><li>• Rapid-acting insulin is available as a cartridge. Make sure to use the correct device for the brand of insulin prescribed, and don't add any other insulin to the cartridge.</li><li>• Assess patient taking insulin concurrently with a thiazolidinedione for signs and symptoms of heart failure. If heart failure develops, provide supportive care, as ordered, and expect the thiazolidinedione to be discontinued or dosage reduced.</li><li>• Know that Fiasp's onset is 5 to 10 minutes.</li></ul>	
Short-acting insulin			
Onset: 30–60 min	Peak: 1.5–4 hr	Duration: 5–8 hr	
<b>Human</b> <ul style="list-style-type: none"><li>• Humulin-R</li><li>• Novolin ge Toronto (CAN)</li><li>• Novolin R</li><li>• ReliOn Novolin R</li></ul> <b>Concentrated</b> <ul style="list-style-type: none"><li>• Humulin R U-500</li></ul>		<ul style="list-style-type: none"><li>• Don't use short-acting insulin if it's cloudy, discolored, or unusually viscous.</li><li>• Use the U-500 strength to treat insulin resistance, as prescribed. Be very careful to use conversion chart if U-500 strength is being administered using U-100 syringes. Also, make sure the right strength of the short-acting insulin is being administered, as severe hypoglycemia and death have occurred because of dispensing, prescribing, and administration errors.</li><li>• Mix short-acting insulin with other insulin types, if needed.</li></ul>	

CATEGORY, SPECIES, AND TRADE NAMES	KEY NURSING CONSIDERATIONS	
Short-acting insulin (continued)		
Onset: 30–60 min	Peak: 1.5–4 hr	Duration: 5–8 hr

- Administer SubQ, I.M., or I.V., as prescribed. Use a continuous SubQ infusion pump, if ordered. The catheter tubing and reservoir insulin should be changed every 48 hours or as specified by the pump manufacturer.
- When giving SubQ or I.M. injections, give the short-acting insulin 15 to 30 minutes before a meal or bedtime snack.
- Assess patient taking insulin concurrently with a thiazolidinedione for signs and symptoms of heart failure. If heart failure develops, provide supportive care, as ordered, and expect the thiazolidinedione to be discontinued or dosage reduced.

<b>Intermediate-acting insulin</b>		
<b>Onset:</b> 1–3 hr	<b>Peak:</b> 4–12 hr	<b>Duration:</b> 12–24 hr

#### Human

- Humulin N
- Novolin ge NPH (CAN)
- Novolin N
- ReliOn Novolin N

- Don't use intermediate-acting insulin if it contains precipitate that is clumped or granular or that clings to the sides of the vial.
- Roll the vial gently between your palms to mix; don't shake it. Also gently turn the prefilled syringe up and down several times before using to achieve a uniform mixture.
- Administer by SubQ injection only, 30 minutes before a meal or bedtime snack.
- Be aware that intermediate-acting insulin rarely produces a blood glucose level that's as close to normal as possible. So expect to mix it with a rapid-acting or short-acting insulin, as prescribed, for optimum blood glucose control.
- Assess patient taking insulin concurrently with a thiazolidinedione for signs and symptoms of heart failure. If heart failure develops, provide supportive care, as ordered, and expect the thiazolidinedione to be discontinued or dosage reduced.

CATEGORY, SPECIES, AND TRADE NAMES	KEY NURSING CONSIDERATIONS
---------------------------------------	----------------------------

## Long-acting insulin

**Onset:** 1–1.5 hr

**Peak:** None

**Duration:** 24–28 hr

### Human

- Basaglar (insulin glargine)
- Detemir (insulin detemir) (CAN)
- Glargine (insulin glargine) (CAN)
- Lantus (insulin glargine)
- Levemir (insulin detemir)

- Don't use long-acting insulin if it contains precipitate that is clumped or granular or that clings to the sides of the vial.
- Do not mix insulin detemir or insulin glargine with another insulin or solution.
- Know that insulin degludec is now approved for use in children age 1 year and over.
- Roll the vial gently between your palms to obtain a uniform mixture; don't shake it.
- Administer by the SubQ route only. Inject insulin glargine once daily at any time, keeping the daily injection time consistent. Inject insulin detemir prescribed once daily with the evening meal or at bedtime; inject insulin detemir prescribed twice daily with the morning meal and with the evening meal, at bedtime, or 12 hours after the morning dose.
- Give insulin glargine at bedtime, if possible, so that additional insulin can be given while patient is awake if effects decline before 24 hours pass. If insulin glargine is given in the morning and its effects don't last 24 hours, hyperglycemia may occur while patient sleeps.
- Assess patient taking insulin concurrently with a thiazolidinedione for signs and symptoms of heart failure. If heart failure develops, provide supportive care, as ordered, and expect the thiazolidinedione to be discontinued or dosage reduced.

## Ultra long-acting insulins

**Onset:** 1–6 hr

**Peak:** None

**Duration:** 36–42 hr

- Toujeo (insulin glargine)
  - Tresiba (insulin degludec)
- Concentrated**
- Tresiba U-200

- Don't use ultra long-acting insulin if it contains precipitate that is clumped or granular or that clings to the sides of the vial.
- Roll the vial gently between your palms to obtain a uniform mixture; don't shake it.
- Be aware that Toujeo contains 3 times as much insulin (300 units/ml) in 1 ml as standard insulin (100 units/ml) and is not for use in children. Toujeo Max SoloStar holds 900 units of insulin glargine—more than any other long-acting insulin pen in the United States—and provides up to 160 units/ml in a single injection and allows for 2-unit increment adjustment. In comparison, Toujeo Solo Star pen contains 450 units of insulin glargine with a maximum dose of 80 units per injection, and dosage must be adjusted in 1-unit increments.
- Administer by the SubQ route only. Inject once daily at any time of day but keep time consistent.
- Assess patient taking insulin concurrently with a thiazolidinedione for signs and symptoms of heart failure. If heart failure develops, provide supportive care, as ordered, and expect the thiazolidinedione to be discontinued or dosage reduced.

CATEGORY, SPECIES, AND TRADE NAMES		KEY NURSING CONSIDERATIONS
<b>Combination insulins</b>		
<b>Onset:</b> 30 min	<b>Peak:</b> 1–12 hr	<b>Duration:</b> 18–24 hr
<b>Human</b> <b>Intermediate-acting/short-acting</b> <ul style="list-style-type: none"> <li>Humalog Mix 25 (CAN)</li> <li>Humalog Mix 50 (CAN)</li> <li>Humalog Mix 75/25</li> <li>Humalog Mix 50/50</li> <li>Humulin 30/70 (CAN)</li> <li>Humulin 70/30</li> <li>Novolin 70/30</li> <li>Novolin ge 30/70 (CAN)</li> <li>Novolin ge 40/60 (CAN)</li> <li>Novolin ge 50/50 (CAN)</li> <li>NovoLog Mix 70/30</li> <li>NovoMix 30 (CAN)</li> <li>ReliOn Novolin 70/30</li> </ul> <b>Ultra long-acting/rapid-acting</b> <ul style="list-style-type: none"> <li>Ryzodeg 70/30</li> </ul>		<ul style="list-style-type: none"> <li>Don't use combination insulin if it contains precipitate that is clumped or granular.</li> <li>Know that Ryzodeg 70/30 is now approved for use in children age 1 year and over.</li> <li>Roll the vial gently between your palms to mix; don't shake it. Also gently turn the prefilled syringe up and down several times before using to achieve a uniform mixture.</li> <li>Administer combination insulin by the SubQ route only, 30 minutes before a meal.</li> <li>Be aware that Canadian and American products contain the same insulin ratio but express it differently. For example, the Canadian Humulin 30/70 and the American Humulin 70/30 both contain 30 units of a short-acting insulin and 70 units of an intermediate-acting insulin. Canadian products list the short-acting insulin first; American products list it second.</li> <li>Know that Ryzodeg 70/30 is composed of 70% long-acting insulin and 30% rapid-acting insulin.</li> <li>Assess patient taking insulin concurrently with a thiazolidinedione for signs and symptoms of heart failure. If heart failure develops, provide supportive care, as ordered, and expect the thiazolidinedione to be discontinued or dosage reduced.</li> </ul>

<b>Combination insulins and glucagon-like peptide-1 receptor agonists</b>		
<b>Onset:</b> 4–6 hr	<b>Peak:</b> 8–20 hr	<b>Duration:</b> 24–28 hr
<b>Long-acting insulin/GLP-1 receptor agonist</b> <ul style="list-style-type: none"> <li>Xultophy 100/3.6 (insulin degludec/liraglutide)</li> <li>Soliqua 100/33 (insulin glargine/lixisenatide)</li> </ul>		<ul style="list-style-type: none"> <li>Know that onset, peak, and duration are determined by the insulin contained in the combination.</li> <li>Expect the same adverse reactions that occur with the individual drugs making up the combination product.</li> <li>Monitor for hypoglycemia that may become life-threatening, especially with lifestyle or medication changes.</li> <li>Monitor renal function in patients with renal impairment or severe GI adverse reactions, as acute kidney injury can occur.</li> <li>Evaluate patient's serum potassium level as ordered, because severe hypokalemia has occurred.</li> <li>Assess patient concurrently taking a thiazolidinedione for signs and symptoms of heart failure. If heart failure develops, provide supportive care, as ordered, and expect dosage to be reduced or drug discontinued.</li> <li>Monitor patient for signs and symptoms of pancreatitis.</li> </ul>

# Oral Allergen Extracts

Prevention of allergy symptoms in patients diagnosed with an allergy has historically required an extended period of desensitization through the administration of injections given in a healthcare setting. Many patients do not have the time or resources required to undergo such a rigorous desensitization process. A new form of treatment using a sublingual route that the patient can self-administer (after the first dose) is now available for certain types of allergens as summarized in the following chart.

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES	NURSING CONSIDERATIONS FOR ALLERGEN EXTRACTS
<b>grass pollen</b> Grastek	To treat grass pollen-induced allergic rhinitis	2800 Bioequivalent Allergy Unit (1 tablet) sublingual once daily	<ul style="list-style-type: none"> <li>Know that allergen extracts are contraindicated in patients with severe, unstable asthma; in patients with a history of any severe systemic allergic reaction, severe local reaction after taking any sublingual allergen immunotherapy, or eosinophilic esophagitis; or in patients with a hypersensitivity to any of the inactive ingredients (gelatin, mannitol, or sodium hydroxide).</li> </ul>
<b>mixed pollens allergen extract</b> Oralair	To treat grass pollen-induced allergic rhinitis	300 Index of Reactivity (1 tablet) sublingual once daily	<ul style="list-style-type: none"> <li>Monitor patient closely for allergic reactions that could become severe and life threatening, such as anaphylaxis and severe laryngopharyngeal constriction.</li> </ul>
<b>ragweed extract</b> Ragwitek	To treat short-term ragweed pollen-induced allergic rhinitis	12 AMB a 1-Unit (1 tablet) sublingual once daily	<ul style="list-style-type: none"> <li>First dose must be administered in a healthcare setting and patient observed for at least 30 minutes after administration for signs and symptoms of an allergic reaction.</li> </ul>

## Less Commonly Used Drugs

### A

acarbose	Glucobay (CAN), Precose
aclidinium bromide	Tudorza Pressair
alfuzosin hydrochloride	Uroxatral, Xatral (CAN)
alirocumab	Praluent
alosetron hydrochloride	Lotronex
alvimopan	Entereg
anakinra	Kineret
apomorphine hydrochloride	Apokyn
arformoterol	Brovana
azilsartan medoxomil	Edarbi

### C

cefadroxil	
cevimeline hydrochloride	Evoxac

### D

dantrolene sodium	Dantrium, Dantrium Intravenous, Revonto, Ryanodex
darunavir ethanolate	Prezista
diflunisal	
dimethyl fumarate	Tecfidera
dupilumab	Dupixent

### E

entacapone	Comtan
eprosartan mesylate	Teveten

etelcalcetide

Parsabiv

etodolac

evolocumab

Repatha

## **F**

fenoprofen calcium

Nalfon

ferumoxytol

Feraheme

## **G**

guanfacine hydrochloride

Intuniv

## **I**

isoproterenol hydrochloride

Isuprel

## **L**

letermovir

Prevymis

liothyronine sodium (L-triiodothyronine,  
sodium L-triiodothyronine, T3, thyronine  
sodium)

Cytomel, Triostat

## **M**

meclofenamate sodium

Meclofen

mepolizumab

Nucala

misoprostol

Cytotec

moexipril hydrochloride

## **N**

neostigmine methylsulfate

Bloxiverz, Neostigmine  
Methylsulfate

## **O**

orlistat

Alli, Xenical

oxacillin sodium

## **P**

paricalcitol  
patiromer sorbitex calcium  
peginesatide  
pentazocine lactate  
pentosan polysulfate sodium  
pentoxifylline  
peramivir  
perampanel  
perindopril erbumine  
perphenazine  
phentolamine mesylate  
physostigmine salicylate  
pindolol  
potassium iodide (KI, SSKI)  
pralidoxime chloride  
(2-PAM chloride, 2-pyridine aldoxime methochloride)  
prasterone  
primidone  
pyrazinamide

## **R**

reteplase  
riluzole  
rotigotine  
rufinamide

## **S**

secnidazole  
secukinumab

Zemplar  
Veltassa  
Omontys  
Talwin  
Elmiron  
Pentoxil, Trental  
Rapivab  
Fycompa  
Aceon  
  
Regitine  
Antilirium  
SynPindol (CAN)  
ThyroSafe, ThyroShield  
Protopam Chloride  
  
Intrarosa  
Mysoline, Sertan (CAN)  
  
Retavase  
Exservan, Rilutek, Tiglutik  
Neupro  
Banzel  
  
Solosec  
Cosentyx

**T**

tacrine hydrochloride  
(tetrahydroaminoacridine, THA)

tapentadol

tapentadol hydrochloride

tedizolid

theophylline

tigecycline

trandolapril

tranexamic acid

Cognex

Nucynta, Nucynta ER

Nucynta Oral Solution

Sivextro

Elixophyllin, Theo- 24,  
Theochron, Theolair,

Uniphyl

Tygacil

Mavik

Cyklokapron, Lysteda

**V**

valacyclovir hydrochloride

valbenazine

valganciclovir hydrochloride

vedolizumab

Valtrex

Ingrezza

Valcyte

Entyvio

**Z**

zanamivir

zileuton

Relenza

Zyflo CR

## Selected Antihistamines

Antihistamines are usually used to relieve immediate hypersensitivity reactions. They're also used as antiemetics (especially in motion sickness), antidyskinetics, antitussives, sedatives, and adjuncts to preoperative or postoperative analgesia.

Antihistamines are contraindicated in patients taking drugs that prolong the QT interval (including itraconazole, ketoconazole, mibefradil, some macrolide antibiotics, quinidine, and zileuton). They're also contraindicated in patients hypersensitive to antihistamines or their components.

The table below includes trade names; usual dosages; and onset, peak, and duration for antihistamines that your patient is most likely to use daily or intermittently to control symptoms of allergic rhinitis. When caring for a patient who takes an antihistamine, individualize your plan of care but be sure to include these general interventions:

- Use antihistamines cautiously in patients with a history of glaucoma, peptic ulcer, or urine retention because anticholinergic effects may worsen these conditions.
- Assess patient for hypokalemia and correct the imbalance, as prescribed, before antihistamine therapy to reduce the risk of arrhythmias.
- Obtain a detailed medication history before antihistamine therapy to help prevent drug interactions.
- Give antihistamines with food if GI distress occurs.
- Urge patient to avoid alcohol and other CNS depressants during antihistamine use because the combination can cause additive CNS depression.
- Monitor blood pressure because these drugs' anticholinergic effects may cause hypertension.
- Be aware that short- and long-acting antihistamines may be combined and H<sub>2</sub> blockers added to increase antihistamine effects.
- Be aware that products containing pseudoephedrine should be used for less than 7 days.

GENERIC AND TRADE NAMES	USUAL ADULT DOSAGE	ONSET, PEAK, AND DURATION
<b>acrivastine</b> Semprex-D (also include pseudoephedrine)	8 mg/60 mg P.O. every 4 to 6 hr. <i>Maximum:</i> Four times a day	<b>Onset:</b> 30 min <b>Peak:</b> Unknown <b>Duration:</b> 6 to 8 hr
<b>azatadine</b> Optimine	1 to 2 mg P.O. every 8 to 12 hr. <i>Maximum:</i> 2 mg in 24 hr	<b>Onset:</b> 15 to 60 min <b>Peak:</b> 4 hr <b>Duration:</b> 12 hr
<b>azelastine</b> Astelin  Astepro 0.1%  Astepro 0.15%	1 to 2 sprays (137 mcg/spray) in each nostril twice daily  1 to 2 sprays (137 mcg/spray) in each nostril twice daily  2 sprays (205.5 mcg/spray) in each nostril once daily	<b>Onset:</b> In 3 hr <b>Peak:</b> Unknown <b>Duration:</b> 12 hr
<b>carbinoxamine maleate</b> Arbinoxa, Palgic  Karbinal ER	4 to 8 mg P.O. three times a day or four times a day. <i>Maximum:</i> 24 mg in 24 hr (Immediate Release)  6 to 16 mg P.O. every 12 hr (Extended Release)	<b>Onset:</b> 30 min <b>Peak:</b> Unknown <b>Duration:</b> 4 hr (Arbinoxa, Palgic), 17 hr (Karbinal ER)

GENERIC AND TRADE NAMES	USUAL ADULT DOSAGE	ONSET, PEAK, AND DURATION
<b>cetirizine hydrochloride</b> Zyrtec Zyrtec D (also includes pseudoephedrine)	5 to 10 mg P.O. daily 5 mg/120 mg every 12 hr	<b>Onset:</b> 30 to 60 min <b>Peak:</b> 1 hr <b>Duration:</b> Up to 24 hr
<b>desloratadine</b> Clarinet, Clarinet Reditabs Clarinet-D 12 hr (also contains pseudoephedrine) Clarinet-D 24 hr (also contains pseudoephedrine)	5 mg P.O. daily 2.5 mg/120 mg P.O. twice daily 2.5 mg/240 mg P.O. once daily	<b>Onset:</b> Unknown <b>Peak:</b> 3 hr (Clarinet Reditabs); unknown for other types <b>Duration:</b> Unknown
<b>fexofenadine hydrochloride</b> Allegra Allegra-D-12 hr (also includes pseudoephedrine) Allegra-D-24 hr (also includes pseudoephedrine)	60 mg P.O. twice daily or 180 mg P.O. daily 60 mg/120 mg P.O. every 12 hr 180 mg/240 mg P.O. once daily	<b>Onset:</b> 1 hr <b>Peak:</b> 2 to 3 hr <b>Duration:</b> 12 hr
<b>levocetirizine dihydrochloride</b> Xyzal	2.5 to 5 mg P.O. daily in evening	<b>Onset:</b> Less than 1 hr <b>Peak:</b> 0.9 hr <b>Duration:</b> 24 hr
<b>loratadine</b> Claritin Claritin-D12 (also includes pseudoephedrine) Claritin-D24 (also includes pseudoephedrine)	10 mg P.O. daily 5 mg/120 mg P.O. every 12 hr 10 mg/240 mg P.O. every 24 hr	<b>Onset:</b> 1 to 3 hr <b>Peak:</b> 8 to 12 hr <b>Duration:</b> At least 24 hr
<b>olopatadine hydrochloride</b> Patanase	2 sprays (665 mcg/spray) in each nostril twice daily	<b>Onset:</b> Unknown <b>Peak:</b> 15 to 120 min <b>Duration:</b> Unknown

## Selected Ophthalmic Drugs

Although less commonly prescribed than oral drugs, drugs instilled into the eyes are frequently brought into the clinical setting by patients with chronic conditions. In most cases, the patient or a family member has administered these preparations at home. Your patient teaching should include a review of proper administration and storage of these drugs. Have the patient or a family member demonstrate proper use of the drug to make sure it will be administered correctly at home. Use this time to reassess the patient's ability to continue self-medication. Also, instruct him to report any changes in the condition being treated, either negative or positive. A properly educated patient not only ensures safe drug administration, but also is more likely to detect adverse reactions that require a dosage reduction or drug discontinuation, thus preventing the development of more serious health problems.

The following chart lists the generic and trade names, FDA-approved indications, and usual adult dosages for those ophthalmic preparations you're most likely to see in your practice setting. The drugs are divided according to therapeutic use.

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
<b>Ophthalmic antibiotics</b>		
<b>bacitracin</b> AK-Tracin	To treat surface bacterial infections affecting the conjunctiva and cornea	1/4-in to 1/2-in strip of ointment applied to conjunctival sac, 1 to 3 times daily or as needed
<b>besifloxacin 0.6%</b> Besivance	To treat bacterial conjunctivitis due to susceptible organisms	1 gtt in affected eye(s) three times a day 4 to 14 hr apart for 7 days
<b>chloramphenicol 1%</b> Diochloram, Pentamycetin /HC, Sopamycetin (CAN)	To treat severe surface bacterial infections affecting the conjunctiva and cornea	Apply small amount of ointment to lower conjunctival sac every 3 to 6 hr and as needed for at least 48 hr after eye resumes normal appearance
<b>ciprofloxacin hydrochloride 0.3%</b> Ciloxan	To treat corneal ulcers due to <i>Pseudomonas aeruginosa</i> , <i>Staphylococcus aureus</i> , <i>S. epidermidis</i> , <i>Streptococcus pneumoniae</i> , and possibly <i>Serratia marcescens</i> and <i>S. viridans</i>  To treat bacterial conjunctivitis due to <i>Haemophilus influenzae</i> , <i>S. aureus</i> , <i>S. epidermidis</i> , <i>S. pneumoniae</i> and <i>S. viridans</i>	2 gtt in affected eye every 15 min for first 6 hr, then 2 gtt every 30 min for rest of first day; on day 2, 2 gtt in affected eye every hr; on days 3 to 14, 2 gtt in affected eye every 4 hr  1 or 2 gtt in conjunctival sac of affected eye every 2 hr while awake for first 2 days and then 1 or 2 gtt every 4 hr while awake for next 5 days; or 1/2-in strip of ointment in affected eye three times a day for 2 days, then twice daily for next 5 days
<b>erythromycin</b> Ilotycin	To treat superficial eye infections involving conjunctiva and/or cornea  As adjunct to prevent ophthalmia neonatorum due to <i>Neisseria gonorrhoeae</i> or <i>Chlamydia trachomatis</i>	1 cm (0.39 in) of ointment applied in infected eye up to 6 times/day, depending on severity of infection  1 cm (0.39 in) of ointment applied in each eye
<b>ganciclovir gel 0.15%</b> Zirgan	To treat acute herpes keratitis (dendritic ulcers)	1 gtt five times daily (about every 3 hr while awake) until corneal ulcer heals; then 1 gtt three times a day for 7 days

### Selected Ophthalmic Drugs (continued)

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
<b>Ophthalmic antibiotics (continued)</b>		
<b>gatifloxacin 0.5%</b> Zymar	To treat bacterial conjunctivitis due to <i>Staphylococcus aureus</i> , <i>S. epidermidis</i>	1 gtt in affected eye every 2 hr while awake, up to eight times daily on day 1; then 1 gtt twice

	<i>aureus</i> , <i>S. epidermidis</i> , <i>Streptococcus mitis</i> , <i>S. pneumoniae</i> , and <i>Haemophilus influenzae</i>	daily on day 1, then 1 gtt twice daily to four times a day while awake on days 2 to 7
<b>gentamicin sulfate</b> Garamycin, Genoptic, Gentacidin, Gentak	To treat bacterial infections such as blepharitis, blepharoconjunctivitis, conjunctivitis, corneal ulcers, dacryocystitis, keratoconjunctivitis, or meibomianitis due to susceptible organisms	1 or 2 gtt every 4 hr or, for severe infection, up to 2 gtt/hr; alternatively, 1/2-in strip of ointment applied to lower conjunctival sac twice daily or three times daily
<b>levofloxacin 0.5%</b> Quixin	To treat bacterial conjunctivitis due to susceptible organisms	On days 1 and 2: 1 or 2 gtt every 2 hr while awake, up to 8 times/day; on days 3 to 7: 1 or 2 gtt every 4 hr while awake, up to 4 times/day
<b>moxifloxacin 0.5%</b> Vigamox	To treat bacterial conjunctivitis due to <i>Staphylococcus aureus</i> , <i>S. epidermidis</i> , <i>S. haemolyticus</i> , <i>S. hominis</i> , <i>Streptococcus pneumoniae</i> , <i>S. viridans</i> group, <i>Haemophilus influenzae</i> , and <i>Chlamydia trachomatis</i>	1 gtt three times a day for 7 days
<b>ofloxacin 0.3%</b> Ocuflox	<p>To treat conjunctivitis due to <i>Staphylococcus aureus</i>, <i>S. epidermidis</i>, <i>Streptococcus pneumoniae</i>, <i>Enterobacter cloacae</i>, <i>Haemophilus influenzae</i>, <i>Proteus mirabilis</i>, and <i>Pseudomonas aeruginosa</i></p> <p>To treat bacterial corneal ulcers due to <i>S. aureus</i>, <i>S. epidermidis</i>, <i>S. pneumoniae</i>, <i>E. cloacae</i>, <i>H. influenzae</i>, <i>Propionibacterium mirabilis</i>, <i>Propionibacterium aeruginosa</i>, <i>Serratia marcescens</i>, and <i>Propionibacterium acnes</i></p>	<p>1 or 2 gtt in conjunctival sac every 2 to 4 hr for first 2 days; then 1 to 2 gtt four times a day for up to 5 more days</p> <p>1 or 2 gtt every 30 min while awake and 1 or 2 gtt every 4 to 6 hr after retiring for 2 days; then 1 or 2 gtt/hr while awake for up to 7 more days; then 1 to 2 gtt four times a day until end of treatment</p>
<b>sulfacetamide sodium 10%</b> Bleph-10, Ocu-Sol 10, Ocu-Sol 15, Ocu-Sol 30, Sodium Sulamyd, Sulf-10, Sulfac 10%	To treat conjunctivitis and other superficial eye infections due to susceptible organisms	1 or 2 gtt solution in lower conjunctival sac every 2 to 3 hr initially, with dosage tapered by increasing time interval between doses as condition improves for up to 10 days; or 1/4-in to 1/2-in strip of ointment in conjunctival sac four times a day and bedtime

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
<b>Ophthalmic antibiotics</b> <i>(continued)</i>		
<b>sulfacetamide sodium ointment 10%, solution 15%</b> Isopto Cetamide	As adjunct to treat trachoma	2 gtt in lower conjunctival sac every 2 hr
<b>tobramycin</b> Tobrasol 0.3%, Tobrex, Tomycline (CAN)	To treat external superficial ocular infections and its adnexa due to susceptible organisms	1 to 2 gtt every 1 to 4 hr, depending on severity of infection; or 1/2-in strip of ointment applied to lower conjunctival sac every 8 to 12 hr for mild to moderate infections or every 3 to 4 hr for severe infections
<b>tobramycin 0.3% (3 mg) and dexamethasone 0.1% (1 mg)</b> TobraDex	To treat steroid-responsive inflammatory ocular conditions for which a corticosteroid is indicated and where superficial bacterial ocular infection or a risk of bacterial ocular infection exists	1 to 2 gtt every 4 to 6 hr; during first 24 to 48 hr, dosage may be increased to 1 to 2 gtt every 2 hr; or apply 1/2-in strip of ointment into the conjunctival sac up to four times a day
<b>Ophthalmic anti-inflammatory drugs</b>		
<b>bromfenac 0.09%</b> Xibrom (0.09%)	To treat postoperative inflammation and reduce ocular pain after cataract extraction	1 gtt in operative eye twice daily starting 24 hr after cataract surgery and continuing through first 2 wk of postoperative period
Bromday (0.09%) Prolensa (0.07%)	To treat postoperative inflammation and reduce ocular pain after cataract extraction	1 gtt in operative eye once daily, starting 24 hr before cataract surgery and continuing through first 2 wk of postoperative period
BromSite	To treat postoperative inflammation and prevent ocular pain associated with cataract extraction	1 gtt in operative eye twice daily (morning and evening) 1 day before surgery, day of surgery, and 14 days postoperatively
<b>dexamethasone</b> Maxidex <b>dexamethasone sodium phosphate 0.1%</b> AK-Dex	To treat allergic conjunctivitis; corneal injury from chemical or thermal burns or from penetration of foreign bodies; inflammatory conditions of the anterior segment of globe, conjunctiva, cornea, or eyelids; iridocyclitis; suppression of graft rejection after keratoplasty; and uveitis	1 or 2 gtt of suspension or solution every hr during day and every 2 hr at night initially. When response occurs, 1 gtt every 4 hr; or apply 1/2-in to 1-in strip of ointment up to four times daily, then tapered to once daily

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
<b>Ophthalmic anti-inflammatory drugs</b> <i>(continued)</i>		
<b>diclofenac sodium 0.1%</b> Voltaren, Voltaren Ophtha (CAN)	To treat postoperative inflammation after removal of cataract  To provide temporary relief of pain and photophobia in corneal refractive surgery	1 gtt in conjunctival sac four times a day, starting 24 hr after surgery through first 2 postoperative wk  1 or 2 gtt in operative eye 1 hr before surgery. Then 1 or 2 gtt 15 min after surgery. Then 1 gtt four times a day, starting 4 to 6 hr after surgery for up to 3 days, as needed
<b>difluprednate 0.05%</b> Durezol	To treat inflammation and pain associated with ocular surgery  To treat endogenous anterior uveitis	1 gtt in conjunctival sac of affected eye(s) four times a day for 2 wk starting 24 hr after surgery. Then 1 gtt twice daily for 1 wk  1 gtt into conjunctival sac of affected eye four times a day for 14 days, then tapered as needed
<b>fluoromethalone 0.1%</b> Fluor-Op, FML Forte, FML Liquifilm, FML S.O.P.	To treat corticosteroid-responsive inflammation of the anterior segment of the globe, bulbar and palpebral conjunctiva, and cornea	1 gtt in conjunctival sac twice daily to four times a day or, in severe conditions, up to every 4 hr during first 1 to 2 days, as needed; or 1.5-in strip of ointment in conjunctival sac once daily to three times a day
<b>fluoromethalone acetate</b> Eflone, Flarex		1 or 2 gtt in conjunctival sac four times daily or, in severe conditions, up to every 2 hr during first 1 or 2 days, as needed
<b>flurbiprofen sodium 0.03%</b> Ocufen	To inhibit intraoperative miosis	1 gtt in affected eye every 30 min, beginning 2 hr before surgery, up to total of 4 gtt
<b>ketorolac tromethamine</b> Acular 0.5%	To relieve ocular itching due to seasonal allergic conjunctivitis	1 gtt in conjunctival sac of each eye four times a day
Acuvail 0.45%	To treat postoperative inflammation in patients who have undergone cataract extraction  To relieve pain and treat postoperative inflammation in patients who have undergone cataract extraction	1 gtt in operative eye four times a day, starting 24 hr after surgery through first 2 postoperative wk  1 gtt in affected eye twice daily, starting 1 day before surgery, continuing through day of surgery and first 2 wk of postoperative period

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
<b>Ophthalmic anti-inflammatory drugs</b> <i>(continued)</i>		
<b>loteprednol etabonate</b> Alrex 0.2%	To relieve seasonal allergic conjunctivitis	1 gtt of 0.2% suspension in affected eyes four times a day
Lotemax 0.5% Inveltyis 1%	To treat postoperative inflammation following ocular surgery	1 or 2 gtt in conjunctival sac of operated eye four times a day, beginning 24 hr after surgery and continuing through first 2 wk of postoperative period
	To treat steroid-responsive inflammatory conditions of the anterior segment of the globe, bulbar and palpebral conjunctiva, and cornea	1 or 2 gtt in conjunctival sac of affected eye four times a day. Initially, dosage may be increased during first week to 1 gtt every hour, as needed
<b>medrysone 1.0%</b> HMS Liquifilm	To treat allergic conjunctivitis, episcleritis, epinephrine sensitivity, and vernal conjunctivitis	1 gtt into conjunctival sac up to every 4 hr
<b>olopatadine hydrochloride 0.1%</b> Patanol	To treat signs and symptoms of allergic conjunctivitis	1 gtt twice daily at 6- to 8-hr intervals
<b>olopatadine hydrochloride 0.7%</b> Pazeo	To treat ocular itching associated with allergic conjunctivitis	1 gtt into conjunctival sac in each affected eye once daily
<b>prednisolone acetate suspension 1%</b> Econopred Plus, Omnipred, Pred Forte, Pred Mild	To treat steroid-responsive inflammation of the anterior segment of globe, cornea, and bulbar and palpebral conjunctiva; to treat corneal injury from chemical, radiation, or thermal burns, or penetration of foreign bodies	1 or 2 gtt in conjunctival sac twice daily to four times a day (suspension) or 1 gtt in conjunctival sac every 4 hr (solution) unless severe, then initially every hr during day and every 2 hr at night until response noted, then decreased to 1 gtt every 4 hr
<b>prednisolone sodium phosphate solution 1%</b> AK-Pred, Prednisol		
<b>rimexolone 1%</b> Vexol	To treat anterior uveitis	1 or 2 gtt in conjunctival sac every hr while awake in first wk; 1 gtt every 2 hr while awake in second wk; then tapered until uveitis resolves
	To treat postoperative inflammation after ocular surgery	1 or 2 gtt in conjunctival sac of affected eye four times a day, starting 24 hr after surgery and continuing through first 2 postoperative wk

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
<b>Ophthalmic cycloplegic mydriatics</b>		
<b>atropine sulfate 1%</b> Isopto Atropine, Minims Atropine (CAN)	To treat acute iritis or uveitis  To produce dilation for cycloplegic refraction	Small strip of ointment applied to conjunctival sac up to twice daily  1 gtt 40 min before refraction. <i>Maximum: 2 gtt</i>
<b>cyclopentolate hydrochloride 0.5%, 1%, 2%</b> AK-Pentolate, Cyclogyl, Minims Cyclopentolate (CAN), Pentolair	To produce mydriasis and cycloplegia required in specific diagnostic procedures	1 or 2 gtt of 0.5%, 1%, or 2% solution in each eye; then 1 or 2 gtt in 5 to 10 min, as needed
<b>homatropine hydrobromide 2%, 5%</b> Isopto Homatropine, Minims Homatropine (CAN)	To dilate pupils for cycloplegic refraction  To treat uveitis	1 or 2 gtt in each eye, repeated in 5 to 10 min as needed  1 or 2 gtt in affected eye(s) every 3 to 4 hr
<b>tropicamide 0.5%, 1%</b> Mydracyl, Opticyl, Tropicacyl	To produce mydriasis  To dilate pupils for cycloplegic funduscopy exam	1 to 2 gtt of 1% solution, repeated in 5 min, as needed  1 to 2 gtt of 0.5% solution in eyes 15 to 20 min before exam, repeated every 30 min as needed
<b>Ophthalmic miotics</b>		
<b>acetylcholine chloride</b> Miochol-E	To produce papillary miosis in cataract surgery, penetrating keratoplasty, iridectomy, and other anterior segment surgery	0.5 to 2 ml gently into anterior chamber before or after sutures secured or after lens placement in cataract surgery
<b>carbachol 0.01%</b> Carbastat, Miostat	To produce papillary miosis in ocular surgery; to reduce intensity of intraocular pressure elevation in first 24 hr after cataract surgery	0.5 ml (solution) into anterior chamber before or after sutures secured or after lens placement in cataract surgery
<b>carbachol 0.75%, 1.5%, 2.25%, 3%</b> Carboptic, Isopto Carbachol	To treat open-angle glaucoma	1 or 2 gtt up to three times a day

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
<b>Ophthalmic miotics</b> <i>(continued)</i>		
<b>naphazoline hydrochloride</b> Ak-Con 0.1%, Albalon 0.1%, Clear Eyes 0.012%, Naphcon A 0.025%, Vasocon 0.05%	To treat ocular congestion, irritation, or itching	1 gtt of 0.1% solution every 3 to 4 hr; or 1 gtt of 0.012% to 0.03% solution up to four times a day for no more than 72 hr
<b>oxymetazoline hydrochloride</b>	To provide relief from eye redness due to minor eye irritations	1 or 2 gtt in conjunctival sac four times a day (at least 6 hr apart) for no more than 72 hr
<b>pilocarpine 1%, 2%, 4%</b> Akarpine, Isopto Carpine, Miocarpine (CAN), Pilocar, Pilopine HS, Pilostat	To treat primary open-angle glaucoma	1 gtt up to four times a day; or 1-cm (0.39-in) ribbon of 4% gel at bedtime
<b>pilocarpine hydrochloride</b> Akarpine, Isopto Carpine, Minocarpine (CAN), Pilocar, Pilopine HS, Pilostat	To treat acute angle-closure glaucoma as emergency therapy	1 gtt of 2% solution every 15 to 60 min for up to four doses
<b>pilocarpine nitrate 1%</b> Minims Pilocarpine (CAN)	To treat mydriasis due to mydriatic or cycloplegic drug therapy	1 gtt of 1% solution
<b>proparacaine hydrochloride 0.5%</b> AK-Taine, Alcaine, Ophthetic, Parcaine	To provide deep anesthesia during cataract extraction To provide anesthesia during removal of eye sutures To provide anesthesia during removal of foreign bodies To provide anesthesia during tonometry	1 gtt every 5 to 10 min for 5 to 7 doses 1 or 2 gtt 2 to 3 min before procedure 1 or 2 gtt in affected eye before surgery 1 or 2 gtt immediately before measurement
<b>tetracaine 0.5%</b> Pontocaine	To provide eye anesthesia (short term)	1 or 2 gtt, as needed

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
<b>Miscellaneous ophthalmic drugs</b>		
<b>alcaftadine 0.25%</b> Lastacaft	To prevent itching associated with allergic conjunctivitis	1 gtt in each eye once daily
<b>apraclonidine</b>	As adjunct in patients on	1 or 2 att in affected eve(s) three

<b>hydrochloride 0.5%</b> Iopidine	maximally tolerated medical therapy who require additional intraocular pressure (IOP) reduction	1 gtt 4 times daily
<b>azelastine hydrochloride 0.05%</b> Optivar	To treat itching of the eye associated with allergic conjunctivitis	1 gtt in affected eye twice daily
<b>bepotastine besilate 1.5%</b> Bepreve	To treat itching of the eye associated with allergic conjunctivitis	1 gtt in affected eye twice daily
<b>betaxolol hydrochloride</b> Betoptic 0.5%, Betoptic S 0.25%	To treat chronic open-angle glaucoma or ocular hypertension	1 or 2 gtt of 0.5% solution twice daily or 1 gtt of 0.25% solution twice daily
<b>bimatoprost 0.01%, 0.03%</b> Lumigan	To reduce elevated IOP in patients with open-angle glaucoma or ocular hypertension	1 gtt in affected eye daily in evening
<b>brimonidine tartrate</b> Alphagan 0.2%, Alphagan P 0.1%, 0.15%	To reduce IOP in open-angle glaucoma or ocular hypertension	1 gtt in affected eye three times daily, about 8 hr apart
<b>brinzolamide 1%</b> Azopt	To reduce IOP in ocular hypertension or open-angle glaucoma	1 gtt three times a day
<b>brinzolamide 1% and brimonidine tartrate 0.2%</b> Simbrinza	To reduce IOP in open-angle glaucoma or ocular hypertension	1 gtt in affected eye three times a day
<b>carteolol hydrochloride 1%</b> Ocupress	To treat chronic open-angle glaucoma or intraocular hypertension	1 gtt in conjunctival sac of affected eye twice daily
<b>cyclosporine 0.09% cyclosporine emulsion 0.05%</b> Restasis	To increase tear production in keratoconjunctivitis sicca	1 gtt every 12 hr

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
<b>Miscellaneous ophthalmic drugs</b> <i>(continued)</i>		
<b>cysteamine 0.44%</b> Cystaran	To treat corneal cystine crystal accumulation in patients with cystinosis	1 gtt in each eye, every waking hr

with cystinosis

<b>dipivefrin hydrochloride 0.1%</b> Ophto-Dipivefrin (CAN), Propine	To reduce IOP in chronic open-angle glaucoma	1 gtt every 12 hr
<b>dorzolamide hydrochloride</b> Trusopt	To treat increased IOP in ocular hypertension or open-angle glaucoma	1 gtt in conjunctival sac of affected eye three times a day
<b>emedastine difumarate</b> Emadine	To treat allergic conjunctivitis	1 gtt in affected eye up to four times a day
<b>ketotifen fumarate</b> Zaditor	To treat allergic conjunctivitis	1 gtt in affected eye twice daily every 8 to 12 hr, but no more than twice daily
<b>latanoprost 0.005%</b> Xalatan, Xelpros	To reduce IOP in ocular hypertension or open-angle glaucoma	1 gtt in conjunctival sac of affected eye daily in evening
<b>latanoprostene bunod 0.024%</b> Vyzulta	To reduce IOP in ocular hypertension or open-angle glaucoma	1 gtt in affected eye(s) once daily in evening
<b>levobunolol hydrochloride</b> AKBeta, Betagan, Novo-Levobunolol (CAN)	To treat chronic open-angle glaucoma or ocular hypertension	1 or 2 gtt of 0.5% solution once daily or 0.25% solution twice daily
<b>levocabastine hydrochloride 0.05%</b> Livostin	To treat signs and symptoms of seasonal allergic conjunctivitis	1 gtt four times a day
<b>lifitegrast 5%</b> Xiidra	To treat dry eye disease	1 gtt twice daily (about 12 hr apart) in each eye
<b>metipranolol 0.3%</b> OptiPranolol	To reduce IOP in ocular hypertension or open-angle glaucoma	1 gtt in affected eye twice daily
<b>nedocromil sodium 2%</b> Alocril	To treat itching associated with both seasonal and perennial allergic conjunctivitis	1 or 2 gtt twice daily

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
<b>Miscellaneous ophthalmic drugs</b> <i>(continued)</i>		
<b>netarsudil 0.02%</b> Rhopressa	To reduce IOP in ocular hypertension or open-angle glaucoma	1 gtt in affected eye(s) once daily in evening
<b>sodium chloride, hypertonic</b> Altachlore, Muro-128 2%, Muro-128 5%, Muroptic-5	To provide temporary relief from corneal edema	1 or 2 gtt every 3 to 4 hr; or 1/4-in of ointment applied every 3 to 4 hr
<b>tafluprost 0.0015%</b> Zioptan	To reduce IOP in ocular hypertension or open-angle glaucoma	1 gtt in conjunctival sac in affected eye(s) once daily in evening
<b>tetrahydrozoline hydrochloride 0.05%</b> Eye-Sine, Murine Plus, Optigene 3, Tetrasine, Visine	To treat allergic conditions, conjunctival congestion, and irritation	1 gtt up to four times a day or as directed
<b>timolol hemihydrate 0.25%, 0.5%</b> Betimol <b>timolol maleate 0.25%, 0.5%</b> Apo-Timop (CAN), Timoptic <b>timolol maleate extended-release gel solution 0.25%, 0.5%</b> Timoptic-XE	To reduce IOP in ocular hypertension or open-angle glaucoma	1 gtt of 0.25% solution in affected eye twice daily, increased to 1 gtt of 0.5% solution, as needed; then 1 gtt daily; or 1 gtt extended-release gel solution in affected eye daily
<b>travoprost 0.004%</b> Travatan	To reduce elevated IOP in patients with open-angle glaucoma or ocular hypertension	1 gtt in affected eye daily in evening
<b>unoprostone isopropyl 0.15%</b> Rescula	To reduce elevated IOP in patients with open-angle glaucoma or ocular hypertension	1 gtt in affected eye twice daily

## Selected Topical Drugs

Topical drugs consist of an active drug prepared in a specified medium that promotes absorption through the skin. Media commonly are chosen based on drug solubility; rate of drug release; ability to hydrate the outer skin layer; ability to enhance penetration; drug stability; and interactions between the chosen medium, skin, and active ingredient.

Topical media include aerosols, creams, gels, lotions, ointments, powders, tinctures, and wet dressings. Aerosols, gels, lotions, and tinctures are convenient for application to the scalp and other hairy areas. Acutely inflamed areas are best treated with drying preparations, such as lotions, tinctures, and wet dressings. Chronic inflammation does well with applications of lubricating preparations, including creams and ointments.

Because of its physical properties, the skin can act as a holding area for many drugs, allowing slow penetration and prolonged duration of action. (This characteristic makes it important to understand the patient's allergies.) However, when administering topical or transdermal drugs that aren't prescribed for a specific location, keep in mind that penetration properties may vary in different areas of the body. For example, the axillae, face, scalp, and scrotum are more permeable than the limbs, and ventral surfaces typically are more permeable than dorsal surfaces.

## Topical Drug Types

Topical drugs are classified as antibacterials, antifungals, antivirals, corticosteroids, retinoids, and other miscellaneous preparations.

- *Antibacterials* may be useful in the early treatment of minor skin infections and wounds. Minor skin infections may respond well to topical drugs applied at the infection site. Minor wounds should be treated at the site and in the immediately surrounding area to prevent other pathogens from colonizing the area.
- *Antifungals* usually are used to treat mucocutaneous infections, such as tinea, primarily ringworm and athlete's foot. Systemic use of antifungals is limited by their potentially toxic adverse effects, most commonly hepatic or renal damage. All fungi are completely resistant to conventional antibacterial drugs.

- *Antivirals* are used to inhibit viral replication. They work by targeting any one of the steps involved in viral replication: penetration into susceptible host cells; uncoating of the viral nucleic acid; synthesis of regulatory proteins, RNA and DNA, and structural proteins; assembly of viral particles; and release of the virus from the cell. Topical antivirals such as penciclovir can shorten the duration of herpetic lesions, lessen lesion pain, and minimize viral shedding.
- *Corticosteroids* reduce the signs and symptoms of inflammation. Topical corticosteroids cause vasoconstriction, probably by suppressing cell degranulation. They also cause decreased cell permeability by reducing histamine release from basal and mast cells.
- *Retinoids*, typically derivatives of vitamin A, are very effective in treating acne vulgaris, although the acne may appear to worsen before it improves. Retinoids are also useful for reducing wrinkles. When applied to the skin, retinoids remain primarily in the dermis; less than 10% of the drug is absorbed into the circulation. Prolonged use of retinoids promotes new dermal growth, new blood vessel formation, and thickening of the epidermis. Because these drugs are absorbed systemically and may have teratogenic effects, they shouldn't be used by pregnant women.
- *Miscellaneous topical drugs* are used to treat a variety of topical skin conditions, including dry skin, ichthyosis, parasitic infestations, psoriasis, and unwanted hair growth.

## Administration Tips

Before you apply a topical drug, clean the site and let it dry. Use gloves or a finger cot during application to prevent the drug from being absorbed through your own skin. Inform your patient of any expected discomfort, such as temporary burning or stinging. After application, cover the site only if required; some topical drugs shouldn't be covered with an occlusive dressing.

Be sure to teach the patient and a family member correct administration technique. Also, review possible adverse reactions, highlighting those that should be reported to the prescriber. Stress the importance of complying with the drug regimen because some topical drugs require weeks or months of therapy to eradicate the underlying condition.

The following table includes the generic and trade names of many commonly prescribed topical drugs as well as their FDA-approved indications and usual adult dosages.

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES

## Antibacterials

<b>azelaic acid cream 20%</b> Azelex <b>azelaic acid foam 15%</b> Finacea Foam <b>azelaic acid gel 15%</b> Finacea Gel	To treat mild to moderate inflammatory acne vulgaris  To treat inflammatory papules and pustules of mild to moderate rosacea	Gently massage thin film into affected area twice daily, morning and evening.  Apply thin layer to entire facial area twice daily, morning and evening.
<b>bacitracin zinc</b>	To treat topical infections; to prevent infection in minor skin wounds such as abrasions, minor burns, and cuts	Apply light dusting of powder or thin film of ointment to affected area once daily to three times a day up to 1 wk.
<b>benzoyl peroxide</b> Benzac, Brevoxyl, Clearasil, Desquam, Fostex, Triaz, ZoDerm	To treat mild to moderate inflammatory acne vulgaris	Apply to affected area once daily, gradually increasing to twice daily or three times a day.
<b>clindamycin and benzoyl peroxide</b> Acanya 1.2%/2.5%, Benzacilin 1%/5%, Duac 1.2%/5%, Nevac 1.2%/5%	To treat acne vulgaris	Apply once or twice daily (morning and/or evening) to affected areas.
<b>clindamycin 1.2% and tretinoin 0.025%</b> Veltin Gel, Ziana Gel	To treat acne vulgaris	Apply pea-sized amount to affected areas once daily in evening.
<b>clindamycin phosphate</b> Cleocin 1%, Clinda-Derm 1%, Clindaget 1%, Clindesse 2%, Clindets 1%, Dalacin T Topical	To treat inflammatory acne vulgaris To treat bacterial vaginosis	Apply to affected area once or twice daily (morning and evening).  1 applicatorful (100 mg) intravaginally at bedtime for 7 days.

Solution 1% (CAN),  
Evoclin 1%

<b>dapsone gel 7.5%</b> Aczone <b>dapsone gel 5%</b> Aczone	To treat acne vulgaris To treat acne vulgaris	Apply pea-sized amount in thin layer to entire face or other affected areas once daily. Apply pea-sized amount in thin layer to entire face or other affected areas twice daily.
<b>erythromycin 1.5%, 2%</b> Akne-Mycin, A/T/S, EryDerm, Erygel, Erythrogel, ETS (CAN), Sans-Acne (CAN), Staticin	To treat inflammatory acne vulgaris	Apply to affected areas once or twice daily (morning and evening).
<b>erythromycin 3% and benzoyl peroxide 5%</b> Benzamycin	To treat moderate inflammatory acne vulgaris	Apply to affected areas twice daily, morning and evening.
<b>gentamicin sulfate</b> Garamycin, G-myticin	To prevent or treat superficial skin infections due to susceptible bacteria; to treat superficial burns	Apply small amount to skin in affected area three or four times a day.
<b>mafenide acetate</b> Sulfamylon	As adjunct to treat second- and third-degree burns	Apply 1/16-in layer aseptically to affected areas once or twice daily.
<b>metronidazole 0.75%, 1%</b> MetroCream, MetroGel, MetroGel-Vaginal, MetroLotion, Noritate	To treat inflammatory papules and pustules of acne rosacea  To treat bacterial vaginosis	Apply thin film to affected area once or twice daily (morning and evening).  1 applicatorful (37.5 mg) intravaginally at bedtime or twice daily for 5 days.
<b>mupirocin 2%</b> Bactroban, Bactroban Cream, Bactroban Nasal, Bactroban	To treat impetigo due to <i>Staphylococcus aureus</i> and <i>Streptococcus pyogenes</i>	Apply to affected areas three times a day up to 10 days.  Apply thin film and cover with a gauze dressing

Ointment, Centany Nasal	<p>To treat secondary infections of traumatic skin lesions due to <i>S. aureus</i> and <i>S. pyogenes</i></p> <p>To eradicate nasal colonization of methicillin-resistant <i>S. aureus</i></p>	<p>three times a day for 10 days.</p> <p>Apply half of the contents of a unit-dose tube to each nostril twice daily for 5 days.</p>
<b>neomycin sulfate</b> Myciguent	To prevent or treat superficial bacterial infections	Rub fingertip-size dose into affected area once daily to three times a day for no more than 1 week.
<b>ozenoxacin</b> Xepi	To treat impetigo due to <i>Staphylococcus aureus</i> or <i>Streptococcus pyogenes</i>	Apply thin layer to affected area (not exceeding 100 cm <sup>2</sup> ) twice daily for 5 days.
<b>povidone-iodine 0.75%, 10%</b> Betadine, Betadine Cream, Betadine Spray	<p>To disinfect wounds and burns</p> <p>To prepare skin for surgical incision</p>	<p>Apply or spray to affected area, as needed.</p> <p>Wet skin with water, then apply 1 cc/20–30 sq inches using 7.5% solution. Lather and scrub site for 5 minutes, then rinse. Follow with 10% solution painted on skin and allowed to dry.</p>
<b>silver sulfadiazine 1%</b> Flamazine (CAN), Silvadene, Thermazine	To prevent and treat wound sepsis in second- and third-degree burns	Apply 1/16-in layer aseptically once to twice daily to clean debrided burns; reapply promptly if removed.
<b>sulfacetamide sodium 10%</b> Klaron	To treat acne vulgaris	Apply thin film twice daily.
<b>Antifungals</b>		
<b>butenafine hydrochloride</b>	To treat tinea corporis, tinea cruris,	Apply to affected surrounding area once

<b>1%</b> Lotrimin Ultra, Mentax Lotrimin Ultra, Mentax	or tinea versicolor To treat interdigital tinea pedis due to <i>Epidermophyton</i> <i>floccosum</i> , <i>Trychophyton</i> <i>mentagrophytes</i> , or <i>T. rubrum</i>	daily for 2 wk. Apply to affected and immediately surrounding area once daily for 4 wk or twice daily for 1 wk.
<b>butoconazole nitrate 2%</b> Femstat 3  Gynazole-1	To treat vulvovaginal mycotic infections caused by <i>Candida</i> species  To treat vulvovaginal infections caused by <i>Candida albicans</i>	1 applicatorful (100 mg) intra- vaginally at bedtime for 3 days.  1 applicatorful (100 mg) intravaginally once anytime day or night; may repeat course for total of 6 days in pregnant women (second and third trimester only).
<b>ciclopirox olamine</b> Loprox Cream 0.77% Loprox Shampoo <b>1% ciclopirox olamine 8%</b> Penlac	To treat candidiasis, tinea corporis, tinea cruris, tinea pedis, and tinea versicolor To treat seborrheic dermatitis To treat onychomycosis of the fingernails and toenails	Massage gently into affected and surrounding area twice daily, morning and evening. Apply 5 ml to scalp (10 ml for long hair), lather and leave on scalp for 3 minutes, then rinse. Repeat twice weekly for 4 weeks with minimum of 3 days between applications. Apply evenly to entire nail surface and surrounding 5 mm of skin at bedtime for up to 48 wk.
<b>clotrimazole</b> Canesten (CAN), Desenex, Femcare, FungiCURE, Fungoid, Gyne- Lotrimin, Lotrimin, Mycelex, Trivagizole	To treat superficial fungal infections (tinea corporis, tinea cruris, tinea pedis, tinea versicolor, candidiasis)  To treat vulvovaginal candidiasis	Apply thin film and massage into affected and surrounding area twice daily, morning and evening, for 2 to 8 wk.  Insert 100-mg vaginal tablet at bedtime for 7 days; or 500-mg vaginal tablet at bedtime for 1

	To treat oropharyngeal candidiasis	day; or 1 applicatorful intravaginally at bedtime for 7 days (or 3 days if using Trivagizole).
	To prevent oropharyngeal candidiasis	Dissolve oral troche over 15 to 30 min 5 times/day for 14 days.
		Dissolve oral troche over 15 to 30 min three times a day for duration of chemotherapy or until corticosteroid dosage is reduced to maintenance levels.
<b>econazole nitrate 1%</b> Ecostatin (CAN) Ecoza	To treat tinea corporis, tinea cruris, tinea pedis, tinea versicolor	Rub into affected area once or twice daily for at least 2 wk (4 wk for tinea pedis).
	To treat cutaneous candidiasis	Rub into affected area twice daily (morning and evening) for 2 wk.
	To treat interdigital tinea pedis	Apply to affected areas once daily for 4 wk.
<b>gentian violet 1%, 2%</b>	To treat candidiasis	Apply 1% solution to affected area two or three times daily for 3 days.
	To help protect against skin infection in minor burns, cuts, or scrapes	Apply small amount of 2% solution to affected area once to three times daily.
<b>ketoconazole 1%, 2%</b> Ketoazole, Nizoral  Ketoazole Shampoo 2%, Nizoral AD Shampoo 1%  Extina 2%, Xolegel 2%	To treat tinea corporis, tinea cruris, tinea pedis, and tinea versicolor due to susceptible organisms; to treat cutaneous candidiasis	Apply thin film to affected and immediately surrounding area daily for at least 2 wk (6 wk for tinea pedis).
		Apply Nizoral AD Shampoo 1% to wet hair, lather, massage for 1 min, leave drug on scalp for 3 min, then rinse and repeat 2 times/wk for 4 up to 8
	To treat tinea versicolor	

	To treat seborrheic dermatitis	<p>wk (with at least 3 days between shampoos), then intermittently, as needed. Alternatively, apply Ketoazole Shampoo 2% one time only to wet hair, lather, massage for 1 min, leave drug on scalp for 5 min, then rinse.</p> <p>Apply to affected and immediately surrounding area twice daily for 4 wk.</p>
<b>luliconazole 1%</b> Luzu	To treat interdigital tinea pedis	Apply to affected area and about 1 in of the immediate surround area(s) once daily for 2 wk.
	To treat tinea cruris and tinea corporis	Apply to affected area and about 1 in of the immediate surrounding area(s) once daily for 1 wk.
<b>miconazole nitrate 2%</b> Fungoid, Micatin, Monistat 1, Monistat 3, Monistat 7, Zeasorb-AF	To treat tinea corporis, tinea cruris, tinea pedis; cutaneous candidiasis; and common dermatophyte infections	Apply cream sparingly (or powder or spray liberally) over affected area twice daily for 2 wk (4 wk for tinea corporis and tinea pedis).
	To treat tinea versicolor	Apply sparingly to affected area daily for 2 wk.
	To treat vulvovaginal candidiasis	Insert into vaginal canal at bedtime for 7 days (100 mg), repeated, as needed; insert 200-mg strength into vaginal canal at bedtime for 3 days; or insert 1,200-mg strength into vaginal canal as a single treatment.
	To treat onychomycosis	

		Brush tincture on affected areas of nail surface, beds, and edges and under nail surface once or twice daily for up to several months; or spray on clean, dry, affected nails, holding actuator down for 1 or 2 sec once or twice daily.
<b>naftifine hydrochloride 2%</b> Naftin	To treat tinea corporis, tinea cruris, and interdigital tinea pedis	Apply to affected area and 1/2-in margin surrounding area once daily for 2 wk.
<b>nystatin</b> Nadostine (CAN), Nilstat, Nystop	To treat cutaneous and mucocutaneous infections due to <i>Candida albicans</i>	Apply cream to affected area twice daily or as indicated; or apply powder twice daily or three times a day.
<b>oxiconazole nitrate</b> Oxistat, Oxizold (CAN)	To treat tinea corporis, tinea cruris, and tinea pedis To treat tinea versicolor	Apply to affected and surrounding area once or twice daily for 2 wk (4 wk for tinea pedis).  Apply cream to affected and surrounding area daily for 2 wk.
<b>selenium sulfide 1%, 2.5%</b> Selsun, Versel (CAN)	To treat tinea versicolor  To treat dandruff and seborrheic scalp dermatitis	Apply to scalp, lather with small amount of water, wait 10 min, then rinse, once daily for 7 days.  Massage into wet scalp, wait 2 to 3 min, rinse, and repeat 2 times/wk for 2 wk, then once daily for 2, 3, or 4 wk.
<b>sulconazole nitrate 1%</b> Exelderm	To treat tinea corporis, tinea cruris, and tinea versicolor	Massage small amount gently into affected and surrounding areas once or twice daily (tinea pedis) for 3 wk.
<b>tavaborole</b>	To treat	Apply to affected toenails,

Kerydin	onychomycosis of the toenails due to <i>Trichophyton mentagrophytes</i> or <i>Trichophyton rubrum</i>	including under the tip of each toenail, once daily for 48 wk.
<b>terbinafine hydrochloride 1%</b> Lamisil	To treat tinea versicolor To treat tinea corporis and tinea cruris  To treat interdigital tinea pedis To treat tinea pedis involving bottom or sides of feet	Apply to affected area twice daily for 1 or 2 wk. Apply thin film to affected area once or twice daily for 1 wk.  Apply between the toes twice daily for 1 wk (interdigital tinea pedis) or to affected area daily for 1 wk. Apply to affected area twice daily (morning and evening) for 2 wk.
<b>terconazole 0.4%, 0.8%</b> Terazol 3, Terazol 7	To treat vulvovaginal candidiasis	1 applicatorful (20 mg) intravaginally at bedtime for 3 days (0.4%) or 1 applicatorful (40 mg) for 7 days (0.8%); or insert 80-mg vaginal suppository at bedtime for 3 consecutive days.
<b>tioconazole</b> GyneCure Ovules (CAN), Vagistat-1	To treat vulvovaginal candidiasis	Insert 1 applicatorful (300 mg) or 1 suppository (300 mg) intravaginally at bedtime as a single dose.
<b>tolnaftate 1%</b> Absorbine Footcare, Aftate for Athlete's Foot, Aftate for Jock Itch, Dr. Scholl's Athlete's Foot, Genaspore, NP-27, Pitrex, Quinsana Plus, Tinactin, Ting, Zeasorb-AF	To treat tinea corporis, tinea cruris, tinea manuum, tinea pedis, and tinea versicolor	Apply to affected and surrounding areas twice daily, morning and evening, for 4 wk (2 wk for tinea cruris); continue for 2 wk after symptoms subside or up to 6 wk.

## Antivirals

<b>acyclovir 5%</b> Zovirax	To treat initial genital herpes and selectively for non-life-threatening mucocutaneous herpes simplex in immunocompromised patients  To treat herpes labialis in immunocompetent patients	Apply ointment every 3 hr (6 times/day) for 7 days. Use finger cot, rubber glove, or applicator stick for both forms to prevent herpetic whitlow.  Apply cream to affected area 5 times a day for 4 days.
<b>docosanol 10%</b> Abreva	To treat recurrent herpes labialis of lips and face	Apply cream gently and completely to affected area five times daily, starting with first visible sign of lesion and continuing until lesion is healed.
<b>penciclovir 1%</b> Denavir	To treat recurrent herpes labialis of lips and face	Apply every 2 hr while awake for 4 days.
<b>Corticosteroids</b>		
<b>alclometasone dipropionate 0.05%</b> Aclovate	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses	Apply thin film to affected area and massage twice daily to three times a day.
<b>amcinonide 0.01%</b> Cyclocort	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses	Apply thin film to affected area and massage twice daily (lotion) or twice daily to three times a day (cream, ointment).
<b>betamethasone benzoate 0.05%</b> Beben (CAN), Uticort	To relieve inflammatory and pruritic manifestations of corticosteroid-	Apply thin film or a few drops to affected area once or twice daily up to 45 g/wk (ointment,

	responsive dermatoses	cream), 50 g/wk (gel), or 50 ml (lotion).
<b>betamethasone dipropionate 0.05%</b> Diprolene, Diprolene AF, Diprosone, Topilene (CAN)	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses	Apply thin film or a few drops to affected area once or twice daily.
<b>betamethasone valerate 0.1%</b> Betatrex, Beta-Val, Luxiq, Valisone	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses	Apply foam to scalp, and massage until foam disappears, twice daily (morning and evening). Apply thin film of cream or ointment 1 to 3 times daily. Apply a few drops of lotion twice daily (morning and evening).
<b>clobetasol propionate 0.025%</b> Impoyz	To treat moderate to severe plaque psoriasis	Apply thin layer to affected skin and rub in gently twice daily, up to 50 g/wk for 2 wk.
<b>clobetasol propionate 0.05%</b> Dermovate (CAN), Embeline, Temovate  Olux	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses  To relieve moderate to severe inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses of scalp	Apply thin film to affected area and rub in gently twice daily (morning and evening), up to 50 g/wk, for 2 wk.  Apply to affected area of scalp twice daily, once in morning and once at night, up to 50 g/wk, for 2 wk.
<b>desonide 0.05%</b> DesOwen, Tridesilon	To relieve inflammatory and pruritic manifestations of corticosteroid-	Apply thin film to affected area twice daily to four times a day.

responsive  
dermatoses

<b>desoximetasone 0.05%</b> Topicort	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses	Apply thin film to affected skin areas twice daily.
<b>diflorasone diacetate 0.05%</b> Florone, Psorcon	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses	Apply thin film to affected area once daily to four times a day.
<b>fluocinolone acetone 0.01%</b> Derma Smooth FS, Fluoderm (CAN), Fluolar (CAN), Fluonid (CAN), Synalar, Synamol (CAN)	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses  To treat seborrheic dermatoses  To treat scalp psoriasis	Apply thin film to affected area twice daily to four times a day.  Use shampoo on scalp daily.  Apply oil to affected areas on scalp and leave overnight.
<b>fluocinonide 0.05%</b> Lidemol (CAN), Lidex	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses	Apply thin film to affected area twice daily to four times a day.
<b>flurandrenolide</b> Cordran 0.05%, Cordran Tape, Drenison 0.05% (CAN)	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses	Apply thin film to affected area and massage twice daily to three times a day; or apply tape every 12 to 24 hr.

<b>fluticasone propionate 0.05%</b> Cutivate	To treat atopic dermatitis; to relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses	Apply thin film once or twice daily (atopic dermatitis) or twice daily (dermatoses).
<b>halcinonide 0.1%</b> Halog	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses	Apply sparingly and massage two to three times a day.
<b>halobetasol propionate 0.05%</b> Ultravate	To treat plaque psoriasis	Apply thin film to affected area and rub in gently twice daily, up to 50 g/wk, for 2 wk.
<b>halobetasol propionate 0.01%</b> Bryhali		Apply thin layer to affected area and rub in gently once daily, up to 50 g/wk and for no longer than 8 wk.
<b>hydrocortisone 0.25%</b> Cetacort	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses	Apply thin film (aerosol foam, cream, lotion, ointment, solution) to affected area once daily to four times a day.

		daily. Do not apply to eyes or lips.
<b>calcipotriene 0.005%</b> Dovonex, Sorilux	To treat plaque psoriasis	Apply cream or scalp lotion in a thin layer twice daily up to 8 wk. Apply thin layer of ointment once or twice daily up to 8 wk.
<b>calcipotriene hydrate 0.005% and betamethasone dipropionate 0.064%</b> Taclonex  Taclonex Scalp	To treat plaque psoriasis  To treat moderate to severe plaque psoriasis of the scalp  To treat psoriasis vulgaris	Apply suspension to affected areas and rub in gently once daily for up to 8 wk.  Apply suspension to affected scalp areas and rub in gently once daily for 2 to 8 wk or until skin clears.  Apply ointment to affected skin; rub in gently and completely once daily for up to 4 wk.
<b>capsaicin 0.025%, 0.075%, 0.1%</b> Capsin, Zostrix	To provide temporary pain relief from rheumatoid arthritis and osteoarthritis; to relieve neuralgias from pain following shingles (herpes zoster) infection	Apply to affected area no more than four times a day.
<b>chlorhexidine gluconate 4%</b> Betasept, Hibiclens	To clean skin wounds  To prepare skin for surgical incision	Rinse area, apply minimal amount to cover, then wash and rinse thoroughly.  Apply liberally to surgical site and swab for at least 2 minutes. Dry with sterile towel and repeat once.
<b>clotrimazole and betamethasone dipropionate 0.05%/1%</b>	To treat symptomatic inflammatory tinea corporis, tinea cruris, and tinea pedis	Apply thin layer and massage cream gently into affected and surrounding skin areas

Lotrisone		twice daily for 2 wk (tinea corporis, tinea cruris) or for 4 wk (tinea pedis).
<b>coal tar</b> Denorex, Pentrax, Zetar, Zetar Shampoo	To treat psoriasis To treat dandruff or scalp seborrhea	Add 15 to 20 ml to lukewarm bath, immerse affected area for 15 to 20 min, and rinse thoroughly 3 to 7 times/wk.  Massage into wet scalp, rinse, repeat application and wait 5 min, then rinse again.
<b>crotamiton 10%</b> Eurax	To treat scabies To treat symptomatic pruritic skin	Massage into cleansed body from chin to soles of feet, and reapply after 24 hr; change bed linens next day, and bathe 48 hr after second dose; repeat in 7 to 10 days if new lesions appear. Massage gently into affected areas until absorbed. Repeat as needed.
<b>desoximetasone 0.05%</b> Topicort	To relieve inflammatory and pruritic manifestations of corticosteroid-responsive dermatoses	Apply thin film twice daily to affected areas.
<b>diclofenac sodium 3%</b> Solaraze	To treat actinic keratoses	Massage gel gently onto affected lesion areas twice daily for 60 to 90 days.
<b>doxepin hydrochloride 5%</b> Zonalon	To treat moderate pruritus associated with atopic dermatitis and chronic lichen simplex	Apply thin film to affected area four times a day (every 3 to 4 hr) for up to 8 days.
<b>eflornithine hydrochloride</b>	To retard unwanted hair growth	Apply thin film to affected area of face and chin

<b>13.9%</b> Vaniqa		twice daily (at least 8 hr apart); don't wash treated area for at least 4 hr.
<b>fluocinolone acetonide 0.01%, hydroquinone 4%, tretinoin 0.05%</b> TRI-LUMA Cream	To treat severe facial melasma	Apply a thin film lightly and uniformly to hyperpigmented areas of melasma including about 1/2 in of skin surrounding each lesion daily at least 30 min before bedtime.
<b>fluorouracil cream</b> Carac 0.5% Efudex 2%, 5% Fluoroplex 1%	To treat actinic and solar keratoses of face and anterior scalp To treat actinic or solar keratosis To treat superficial basal cell carcinoma To treat actinic or solar keratosis	Apply to lesions twice daily for 4 wk. Apply to lesions twice daily for 2 to 4 wk. Apply 5% preparation twice daily in sufficient amounts to cover lesions for up to 12 wks. Apply to lesions twice daily for 2 to 6 wk.
<b>glycopyrronium 2.4%</b> Qbrexza	To treat primary axillary hyperhidrosis	Apply once daily to both axillae using a single cloth.
<b>hexachlorophene 3%</b> PhisoHex	To use as a surgical scrub To use for bacteriostatic cleansing	Wet hands and forearms with water, apply 5 ml of solution and rub into a copious lather for 3 min, then rinse; repeat once. Wet hands with water, pour 5 ml into palm and work up a lather, then apply to area to be cleaned. Rinse thoroughly.
<b>hydrocortisone acetate 1%, polymyxin B sulfate, bacitracin zinc, and neomycin sulfate</b> Cortisporin	To treat corticosteroid-responsive dermatoses associated with secondary bacterial infection	Apply small amount to affected areas twice daily to four times a day for up to 7 days.
<b>hydroquinone</b>	To treat	Apply twice daily to the

Claripel 4%, Eldopaque 2%, Eldoquin 2% and 4%, Melanex 3%	hyperpigmentation and melanin	affected areas for no longer than 2 mo.
<b>imiquimod 2.5%, 3.75%</b> Zyclara	To treat facial or scalp actinic keratoses To treat external genital and perianal warts	Apply 2.5% or 3.75% to affected area daily for two 2-wk treatment cycles separated by a 2-wk no- treatment period. Apply 3.75% cream to the external genital and perianal warts until total clearance or up to 8 wk.
<b>imiquimod 5%</b> Aldara	To treat external genital and perianal warts To treat actinic keratosis on face and scalp To treat superficial basal cell carcinoma	Apply thin layer to affected area and rub in 3 times/wk at bedtime for up to 16 wk; remove with soap and water after 6 to 10 hr. Apply to affected area on face or scalp (but not both concurrently) for 16 wk. Apply to affected area 5 times per wk for 6 wk prior to bedtime and leave on skin for about 8 hrs, then wash area with mild soap and water.
<b>ingenol mebutate 0.015%, 0.05%</b> Picato	To treat actinic keratosis	Apply 0.015% gel to face and scalp once daily for 3 consecutive days; apply 0.05% gel to trunk and extremities once daily for 2 consecutive days.
<b>ivermectin 0.5%</b> Sklice	To treat head lice	Apply to dry hair in amount sufficient to coat the hair and scalp thoroughly; leave on for 10 minutes, then rinse off with water.
<b>ivermectin 1%</b> Soolantra	To treat inflammatory lesions of rosacea	Apply pea-sized amount for each affected area of the face (chin, each

		cheek, forehead) once daily.
<b>lidocaine 2.5% and prilocaine 2.5%</b> EMLA	For local anesthesia	Apply 1 disk or thick layer of 2- to 2.5-g cream occlusively for at least 1 hr before the start of routine procedure or 2 hr before the start of painful procedure.
<b>malathion 0.5%</b> Ovide	To treat pediculus humanus capitis (head lice and their ova) of scalp hair	Apply to dry hair in amount just sufficient to wet the hair and scalp thoroughly; then let hair dry naturally. After 8 to 12 hr, shampoo and rinse hair and use a fine-toothed comb to remove dead lice and eggs. If lice are still present after 7 to 9 days, repeat application.
<b>mequinol 2%, tretinoin 0.01%</b> Solage	To treat solar lentigines	Apply solution twice daily, morning and evening, at least 8 hr apart. Avoid application to surrounding skin, and do not bathe for 6 hr after application.
<b>nitroglycerin 0.4%</b> Rectiv	To treat moderate to severe pain associated with chronic anal fissure	Apply 1 in of ointment intra-anally every 12 hr for up to 3 wk.
<b>oxybutynin chloride 10%</b> Gelnique	To treat overactive bladder with symptoms of urge urinary incontinence, urgency, and frequency	Apply 1 sachet of gel or 1 activation of metered-dose pump once daily to clean, dry, intact skin on abdomen, upper arms/shoulders, or thighs.
<b>permethrin 1%</b> Nix	To prevent or treat head lice	Wash and dry hair, saturate scalp, leave on hair for 10 min, then rinse; remove nits with provided comb; repeat in 7 days if living mites are still present.

<b>permethrin 5%</b> Acticin, Elimite	To treat scabies	Massage into skin from head to soles of feet, and remove after 8 to 10 hr; repeat in 14 days if living mites are still present.
<b>pimecrolimus 1%</b> Elidel	To treat mild-to-moderate atopic dermatitis as a second-line therapy	Apply to affected areas twice daily for up to 6 wk.
<b>podofilox 0.5%</b> Condylox	To treat anogenital warts (gel)  To treat external genital warts (gel or solution)	Apply gel to anogenital warts for 3 days, then withhold for 4 days; repeat cycle up to four times.  Apply gel or solution to external genital warts every 12 hr in the morning and evening for 3 days, then withhold for 4 days; repeat cycle up to four times.
<b>pyrethrin and piperonyl butoxide</b> Licide, Pronto, RID	To treat body, head, and pubic lice	Apply to dry hair or affected body area. Massage through all hairy areas until hair is wet. Leave on hair for 10 min; then wash with warm water and rinse thoroughly. Repeat in 7 to 10 days.
<b>spinosad 0.9%</b> Natroba	To treat head lice	Apply to dry scalp and hair using only the amount needed to cover the scalp and hair. Rinse off with warm water after 10 min. Repeat in 7 days if live lice are still seen.
<b>tacrolimus 0.03% and 0.1%</b> Protopic	To treat moderate to severe atopic dermatitis in patients unresponsive to other therapies	Apply thin layer to affected areas twice daily, rubbing in gently and completely.

**urea 41%, 45%**  
Utopic

To treat  
hyperkeratotic  
conditions

Apply to affected area  
twice daily and rub in.

## Selected Combination Antiviral Drugs

Combination antiviral drugs are used to treat viral infections, such as human immunodeficiency virus (HIV) and hepatitis C infections.

The following table lists the generic and trade names, indications, and usual adult dosages for some commonly used combination antivirals. Although you must individualize your care for a patient who receives an antiviral, be sure to include these general interventions in your plan of care:

- Avoid administering HIV drugs all at once.
- If patient takes an antacid, administer it 1 hour before or 2 hours after an antiviral because antacids may reduce antiviral absorption.
- Monitor hepatic enzyme levels to detect elevations and help prevent hepatotoxicity.
- Monitor BUN and serum creatinine levels to detect signs of impaired renal function.
- Monitor I.V. injection site for pain or phlebitis, which may result from the high pH of reconstituted solutions.
- Assess the immunosuppressed patient for opportunistic infections during antiviral therapy.
- Inform female patient that oral contraceptives may be ineffective when taken with HIV drugs. Suggest alternate contraceptive methods.

GENERIC AND TRADE NAMES	INDICATIONS	USUAL ADULT DOSAGES
Antivirals used for HIV infection		
<b>abacavir sulfate, dolutegravir, and lamivudine</b> Triumeq	To treat HIV-1 infection	600 mg abacavir, 50 mg dolutegravir, and 300 mg lamivudine (1

		tablet) P.O. once daily
<b>abacavir sulfate and lamivudine</b> Epzicom	As adjunct to treat HIV-1 infection	600 mg abacavir and 300 mg lamivudine (1 tablet) P.O. daily
<b>abacavir sulfate, lamivudine, and zidovudine</b> Trizivir	As adjunct or as monotherapy to treat HIV-1 infection	300 mg abacavir, 150 mg lamivudine, and 300 mg zidovudine (1 tablet) P.O. twice daily
<b>atazanavir sulfate and cobicistat</b> Evotaz	As adjunct to treat HIV-1 infection	300 mg atazanavir and 150 mg cobicistat (1 tablet) P.O. once daily
<b>bictegravir, emtricitabine, and tenofovir alafenamide</b> Biktarvy	To treat HIV-1 infection	50 mg bictegravir, 200 mg emtricitabine, and 25 mg tenofovir alafenamide (1 tablet) P.O. once daily.
<b>darunavir and cobicistat</b> Prezcobix	As adjunct to treat HIV-1 infection	800 mg darunavir and 150 mg cobicistat (1 tablet) P.O. once daily
<b>darunavir, cobicistat, emtricitabine, and tenofovir alafenamide</b> Symtuza	To treat HIV-1 infection	800 mg darunavir, 150 mg cobicistat, 200 mg emtricitabine, and 10 mg

		tenofovir alafenamide (1 tablet) P.O. once daily.
<b>doravirine, lamivudine, and tenofovir disoproxil fumarate</b> Delstrigo	To treat HIV-1 infection	100 mg doravirine, 300 mg lamivudine, and 300 mg tenofovir disoproxil fumarate (1 tablet) P.O. once daily
<b>efavirenz, emtricitabine, and tenofovir disoproxil fumarate</b> Atripla	As adjunct or monotherapy to treat HIV-1 infection in adults weighing at least 40 kg (88 lb) or more	600 mg efavirenz, 200 mg emtricitabine, and 300 mg tenofovir disoproxil fumarate (1 tablet) P.O. once daily, at bedtime
<b>efavirenz, lamivudine, and tenofovir disoproxil fumarate</b> Symfi Symfi Lo	To treat HIV-1 infection in patients weighing at least 40 kg (88 lb) or more  To treat HIV-1 infection in adults and children weighing at least 35 kg (77 lb)	600 mg efavirenz, 300 mg lamivudine, and 300 mg tenofovir disoproxil fumarate (1 tablet) P.O. once daily 400 mg efavirenz, 300 mg lamivudine, and 300 mg tenofovir disoproxil fumarate (1 tablet) P.O. once daily

<b>elvitegravir, cobicistat, emtricitabine, tenofovir alafenamide</b> Genvoya	To treat HIV-1 infection	150 mg elvitegravir, 150 mg cobicistat, 200 mg emtricitabine, and 10 mg tenofovir alafenamide (1 tablet) once daily
<b>elvitegravir, cobicistat, emtricitabine, tenofovir disoproxil fumarate</b> Stribild	To treat HIV-1 infection	150 mg elvitegravir, 150 mg cobicistat, 200 mg emtricitabine, 300 mg tenofovir (1 tablet) P.O. once daily with food
<b>emtricitabine, rilpivirine, tenofovir disoproxil fumarate</b> Complera	To treat HIV-1 infection	200 mg emtricitabine, 25 mg rilpivirine, 300 mg tenofovir (1 tablet) P.O. daily with meal
<b>emtricitabine, rilpivirine, tenofovir alafenamide</b> Odefsey	To treat HIV-1 infection	200 mg emtricitabine, 25 mg rilpivirine, and 25 mg tenofovir alafenamide (1 tablet) P.O. once daily
<b>emtricitabine and tenofovir alafenamide</b> Descovy	To treat HIV-1 infection	200 mg emtricitabine and 25 mg tenofovir alafenamide (1 tablet) P.O.

		once daily in combination with other antiretrovirals
<b>emtricitabine and tenofovir disoproxil fumarate</b> Truvada	As adjunct to treat HIV-1 infection in patients weighing at least 17 kg (37.4 lb)	<p><i>Weighing at least 35 kg (77 lb):</i> 200 mg emtricitabine and 300 mg tenofovir disoproxil fumarate (1 tablet) P.O. once daily</p> <p><i>Weighing 28 kg (61.6 lb) to less than 35 kg (77 lb):</i> 167 mg emtricitabine and 250 mg tenofovir disoproxil fumarate (1 tablet) P.O. once daily</p> <p><i>Weighing 22 kg (48.4 lb) to less than 28 kg (61.6 lb):</i> 133 mg emtricitabine, 200 mg tenofovir disoproxil fumarate (1 tablet) P.O. once daily</p> <p><i>Weighing 17 kg (37.4 lb) to less than 22 kg (48.4 lb):</i> 100 mg emtricitabine and 150 mg</p>

		tenofovir disoproxil fumarate (1 tablet) P.O. once daily
<b>lamivudine and raltegravir</b> Dutrebis	As adjunct to treat HIV-1 infection	150 mg lamivudine and 300 mg raltegravir (1 tablet) P.O. twice daily
<b>lamivudine and tenofovir disoproxil fumarate</b> Cimduo	As adjunct to treat HIV-1 infection in patients weighing 35 kg (77 lb) or more	300 mg lamivudine and 300 mg tenofovir disoproxil fumarate (1 tablet) P.O. once daily
<b>lamivudine and zidovudine</b> (3TC/AZT, 3TC/ZDV) Combivir	As adjunct to treat HIV-1 infection in patients who weigh 50 kg (110 lb) or more	150 mg of lamivudine and 300 mg of zidovudine P.O. twice daily
<b>lopinavir and ritonavir</b> Kaletra	As adjunct to treat HIV-1 infection	800 mg lopinavir and 200 mg ritonavir once daily or 400 mg lopinavir and 100 mg ritonavir P.O. twice daily
<b>Antivirals used for hepatitis C infection</b>		
<b>elbasivir and grazoprevir</b> Zepatier	To treat chronic hepatitis C with genotype 1 or 4	50 mg elbasivir and 100 mg grazoprevir (1 tablet) P.O. once daily
<b>ledipasvir and sofosbuvir</b>	To treat chronic hepatitis C genotype 1, 4, 5, or 6 in patients	90 mg ledipasvir and

Harvoni	without cirrhosis or with compensated cirrhosis; as adjunct to treat chronic hepatitis C genotype 1 in patients with decompensated cirrhosis or genotype 1 or 4 in liver transplant recipients without cirrhosis or compensated cirrhosis	400 mg sofosbuvir (1 tablet) P.O. once daily
<b>ombitasvir, paritaprevir, and ritonavir</b> Technivie	As adjunct to treat chronic hepatitis C genotype 4 in patients without cirrhosis	25 mg ombitasvir, 150 mg paritaprevir, and 100 mg ritonavir (2 tablets) P.O. once daily in morning
<b>sofosbuvir and velpatasvir</b> Epclusa	To treat chronic hepatitis C genotype 1, 2, 3, 4, 5, or 6 in patients with compensated cirrhosis or without cirrhosis, or with decompensated cirrhosis when used in combination with ribavirin	400 mg sofosbuvir and 100 mg velpatasvir (1 tablet) P.O. once daily
<b>sofosbuvir, velpatasvir, and voxilaprevir</b> Vosevi	To treat chronic hepatitis C genotype 1, 2, 3, 4, 5, or 6 in patients with compensated cirrhosis or without cirrhosis in patients previously treated with an HCV regimen containing an NS5A inhibitor or genotype 1a or 3 infection previously treated with an HCV regimen containing sofosbuvir without an NS5A inhibitor	400 mg sofosbuvir, 100 mg velpatasvir, and 100 mg voxilaprevir (1 tablet) P.O. once daily

# Common Cancers and Antineoplastic Drug Therapy

Antineoplastic drugs are commonly used in the treatment of many types of cancer today. Most of these drugs work by inhibiting cell proliferation, which leads to cell death. They're most effective at killing actively dividing cells.

Cell-specific antineoplastics exert their actions during one or more phases of the cell cycle. S-phase antineoplastics interfere with deoxyribonucleic acid (DNA) synthesis; M-phase drugs interfere with the formation of microtubules and disrupt mitosis.

Most antineoplastics impair DNA in one of the following four ways:

- preventing separation of DNA strands
- inhibiting DNA repair
- mimicking DNA bases
- disrupting the triplicate codons or producing oxygen-free radicals that damage the DNA.

Antineoplastic drugs are cytotoxic, which means that they affect both neoplastic cells and normal cells. As a result, they may cause serious and sometimes life-threatening adverse reactions.

Antineoplastics are most harmful to normal cells that exhibit rapid activity and growth, such as bone marrow tissue, the epithelium of the GI mucosa, and hair follicles. When these drugs suppress bone marrow activity, the patient may develop leukopenia, thrombocytopenia, or anemia. When they affect the GI mucosa, the patient may experience nausea, vomiting, anorexia, bowel dysfunction, and mucosal ulcerations. When antineoplastic drugs affect the hair follicles, the result is hair loss (alopecia), one of the most common adverse reactions. Although not life-threatening, hair loss can be emotionally traumatic for patients, especially women. However, the recent FDA approval of scalp-cooling caps to spare hair loss as a result of chemotherapy can help to prevent baldness in many patients.

The following chart lists the most common cancers (excluding nonmelanoma skin cancers) in the order of prevalence according to the American Cancer Society. The most common type of cancer for women is breast cancer and the most common type of cancer for men is prostate cancer.

The antineoplastic drugs that may be used initially to treat these common cancers are listed under each cancer type. Adult dosages for these cancers are usually based on body weight in kilograms and subsequent dosages are adjusted according to the type and severity of adverse reactions that have occurred during the last cycle. Antineoplastic therapy is given in cycles of a certain number of days or weeks based on protocol for that type of cancer and the patient's reaction to the drugs given during the previous cycle. For example, if the patient experiences bone marrow suppression from the previous cycle, the degree of suppression will determine if the antineoplastic drug regimen is withheld until the blood counts improve or the dosages of the drugs used are decreased.

It is imperative that the nurse monitor patients receiving antineoplastic therapy closely for adverse reactions, because reactions can occur suddenly and can often become serious or life-threatening quickly.

CANCER TYPE	COMMON ANTINEOPLASTIC DRUG THERAPY
-------------	------------------------------------

**CANCER  
TYPE****COMMON ANTINEOPLASTIC DRUG THERAPY**

Breast  
cancer

- Anthracyclines: Examples include doxorubicin (Adriamycin) and epirubicin (Ellence)
- Taxanes: Examples include paclitaxel (Taxol) and docetaxel (Taxotere)
- 5-fluorouracil (5-FU)
- carboplatin (Paraplatin)
- cyclophosphamide (Cytosan)

Combinations of 2 or 3 of these drugs are most often administered.

Advanced breast cancer

- Anthracyclines: Examples include doxorubicin (Adriamycin), epirubicin (Ellence), and pegylated liposomal doxorubicin (Doxil)
- Platinum agents: Examples include carboplatin (Paraplatin) and cisplatin (Platinol, Platinol-AQ)
- Taxanes: Examples include albumin-bound paclitaxel (Abraxane), docetaxel (Taxotere), and paclitaxel (Taxol)
- capecitabine (Xeloda)
- eribulin (Halaven)
- gemcitabine (Gemzar)
- ixabepilone (Ixempra)
- nab-paclitaxel (Abraxane)
- vinorelbine (Navelbine)

Most often, advanced breast cancer is treated with a single antineoplastic agent, although a combination such as carboplatin plus paclitaxel may be administered depending on the clinical status of the patient.

## Selected Antihypertensive Combinations

Antihypertensive drugs are used along with life-style changes to manage hypertension. Anti- hypertensive combinations, which commonly include one or two antihypertensives and a diuretic, are used to simplify patients' drug regimens and, in some cases, to enhance drug actions.

The table below lists the generic and trade names; functional classes; usual adult dosages; and onset, peak, and duration for commonly used antihypertensive combinations. For information about the mechanisms of action, interactions, adverse reactions, and nursing considerations related to antihypertensive combinations, review the entries for the specific antihypertensives and diuretics that they contain.

ANTIHYPERTENSIVE COMBINATION TRADE NAMES	ANTIHYPERTENSIVE GENERIC NAMES	DIURETIC GENERIC NAMES
Aldoril-15	methyldopa 250 mg	hydrochlorothiazide (HCTZ) 15 mg
Aldoril-25	methyldopa 250 mg	HCTZ 25 mg
Aldoril D30	methyldopa 500 mg	HCTZ 30 mg
Aldoril D50	methyldopa 500 mg	HCTZ 50 mg
Amturnide 150/5/12.5	aliskiren 150 mg, amlodipine 5 mg	HCTZ 12.5 mg
Amturnide 300/5/12.5	aliskiren 300 mg, amlodipine 5 mg	HCTZ 12.5 mg
Amturnide 300/5/25	aliskiren 300 mg, amlodipine 5 mg	HCTZ 25 mg
Amturnide 300/10/12.5	aliskiren 300 mg, amlodipine 10 mg	HCTZ 12.5 mg
Amturnide 300/10/25	aliskiren 300 mg, amlodipine 10 mg	HCTZ 25 mg
Apresazide 25/25	hydralazine hydrochloride (HCL) 25 mg	HCTZ 25 mg
Apresazide 50/50	hydralazine HCl 50 mg	HCTZ 50 mg
Apresazide 100/50	hydralazine HCl 100 mg	HCTZ 50 mg
Atacand HCT 16/12.5	candesartan cilexetil 16 mg	HCTZ 12.5 mg
Atacand HCT 32/12.5	candesartan cilexetil 32 mg	HCTZ 12.5 mg
Atacand HCT 32/25	candesartan cilexetil 32 mg	HCTZ 25 mg
Avalide-150	irbesartan 150 mg	HCTZ 12.5 mg
Avalide-300	irbesartan 300 mg	HCTZ 12.5 mg
Azor 5/20	amlodipine 5 mg, olmesartan 20 mg	None
Azor 5/40	amlodipine 5 mg, olmesartan 40 mg	
Azor 10/20	amlodipine 10 mg, olmesartan 20 mg	
Azor 10/40	amlodipine 10 mg, olmesartan 40 mg	
Benicar HCT 20/12.5	olmesartan medoxomil 20 mg	HCTZ 12.5 mg
Benicar HCT 40/12.5	olmesartan medoxomil 40 mg	HCTZ 12.5 mg
Benicar HCT 40/25	olmesartan medoxomil 40 mg	HCTZ 25 mg
Capozide 25/15	captopril 25 mg	HCTZ 15 mg
Capozide 25/25	captopril 25 mg	HCTZ 25 mg
Capozide 50/15	captopril 50 mg	HCTZ 15 mg
Capozide 50/25	captopril 50 mg	HCTZ 25 mg

FUNCTIONAL CLASSES	USUAL ADULT DOSAGES	ONSET, PEAK, AND DURATION
Centrally acting antiadrenergic and thiazide diuretic	1 tab twice daily or three times daily 1 tab twice daily 1 tab daily 1 tab daily	<b>Onset:</b> Unknown <b>Peak:</b> 4 to 6 hr <b>Duration:</b> 12 to 24 hr

## Selected Obstetrical Drugs

Obstetrical drugs are used during pregnancy for a variety of reasons, such as control of nausea and vomiting, pain relief, and assistance in the labor and delivery process. Drugs used to control nausea and vomiting throughout pregnancy and analgesics used to provide pain relief, especially during the labor and delivery process, are covered in the main section of the *Nurse's Drug Handbook*. While other drugs may be used during pregnancy, not all have FDA approval for such use. For example, misoprostol, a synthetic prostaglandin, is used to treat ulcers. However, it may also be used for indications not approved by the FDA, such as assisting in the termination of a pregnancy, evacuation of the uterine contents in a missed abortion, and dilating the cervix prior to labor. These uses are considered "off-label" uses because they have not been FDA approved. In adherence with the standard of only including FDA-approved indications in the *Nurse's Drug Handbook*, following are selected obstetrical drugs that are FDA approved for use with pregnancy issues.

GENERIC NAME AND TRADE NAME	INDICATIONS	ADULT DOSAGES
<b>dinoprostone</b> Cervidil, Prepidil, Prostin E2	Initiation and/or continuation of cervical ripening in patients at or near term in whom there is a medical or obstetrical indication for the induction of labor	10 mg intravaginally designed to release 0.3 mg/hr of the drug over a 12- hr period; removed upon onset of active labor or 12 hr after insertion
<b>hydroxyprogesterone caproate</b> Makena	To reduce risk of preterm birth in women who are carrying only one fetus and who have a history of singleton	250 mg (1 ml) I.M. once weekly begun between 16 wk, 0 days and 20 wk, 6 days of gestation and continued weekly until wk 37 or delivery, whichever comes first

	spontaneous preterm birth	
<i>oxytocin</i> Pitocin	To initiate or improve uterine contractions in situations where there are fetal or maternal concerns, so as to achieve a vaginal delivery	<i>Initial:</i> 0.5 mU (milliunits)/min to 1 mU/min I.V., increased in increments of 1 to 2 mU/min every 30 to 60 min, as needed; once desired frequency of contractions has been reached and labor has progressed to 5 to 6 cm dilation, dosage may be decreased by 1 to 2 mU/min every 30 to 60 min
	To produce uterine contractions during the third stage of labor and to control postpartum bleeding or hemorrhage To treat incomplete, inevitable, or elective abortion	10 to 40 units added to existing intravenous solution being infused (maximum 40 units to 1,000 ml of solution) and infused at a rate to sustain uterine contraction and control atony  <i>Alternatively,</i> 10 units (1 ml) I.M. after delivery of placenta  <i>Initial:</i> I.V. infusion rate highly individualized (10 units mixed in 500 ml of saline or 5% dextrose-in-water solution)  <i>Maximum:</i> 30 units in a 12-hr period
<b>ulipristal acetate</b> ELLA	To prevent pregnancy following unprotected intercourse or contraceptive failure	30 mg (1 tablet) as soon as possible within 120 hours (5 days) after unprotected intercourse or contraceptive failure

# Vitamins

As you know, an adequate daily intake of vitamins is essential to vital bodily functions, such as embryonic development (vitamin A), regulation of serum calcium and phosphate (vitamin D), and blood clotting (vitamin K).

Vitamins are classified as one of two types: fat soluble (vitamins A, D, E, and K) and water soluble (vitamin C and all forms of vitamin B). Fat-soluble vitamins can accumulate in body tissue over time; when excessive amounts are ingested through diet or supplementation, severe and life-threatening toxicity can develop. Water-soluble vitamins don't accumulate in the body; they are excreted daily so that toxicity is not usually a concern with excessive intake.

The following chart lists the generic and trade names of fat-soluble and water-soluble vitamins, the recommended daily intake to prevent vitamin deficiency, dosages when deficiency occurs, other indications and dosages for vitamin therapy, and guidelines for parenteral administration of vitamins.

GENERIC AND TRADE NAMES	RECOMMENDED DAILY INTAKE
<b>vitamin A (retinol)</b> Aquasol A	<p><b>Adult men and boys over age 10.</b> 1,000 mcg/day.</p> <p><b>Adult women and girls over age 10.</b> 800 mcg/day.</p> <p><b>Pregnant women.</b> 800 mcg/day. (900 mcg/day [CAN].)</p> <p><b>Breastfeeding women.</b> 1,200 to 1,300 mcg/day. (1,200 mcg/day [CAN].)</p> <p><b>Children ages 7 to 10.</b> 700 mcg/day. (700 to 800 mcg/day [CAN].)</p> <p><b>Children ages 4 to 7.</b> 500 mcg/day.</p> <p><b>Neonates and children to age 4.</b> 375 to 400 mcg/day. (400 mcg/day [CAN].)</p>
<b>vitamin B<sub>1</sub> (thiamine hydrochloride)</b> Betaxin (CAN), Bewon (CAN), Biamine	<p><b>Adult men and boys over age 10.</b> 1.2 to 1.5 mg/day. (0.8 to 1.3 mg/day [CAN].)</p> <p><b>Adult women and girls over age 10.</b> 1 to 1.1 mg/day. (0.8 to 0.9 mg/day [CAN].)</p> <p><b>Pregnant women.</b> 1.5 mg/day. (0.9 to 1 mg/day [CAN].)</p> <p><b>Breastfeeding women.</b> 1.6 mg/day. (1 to 1.2 mg/day [CAN].)</p>

## OTHER INDICATIONS AND DOSAGES

### TO TREAT VITAMIN A DEFICIENCY

CAPSULES, ORAL SOLUTION, TABLETS

**Adults and adolescents.** Dosage individualized based on severity of deficiency, as prescribed.

I.M. INJECTION

**Adults and children age 8 and over.** 15,000 to 30,000 retinol equivalent (RE)/day (50,000 to 100,000 IU/day) for 3 days, followed by 15,000 RE/day (50,000 IU/day) for 2 wk.

**Children ages 1 to 8.** 1,500 to 4,500 RE/day (5,000 to 15,000 IU/day) for 10 days; for severe deficiency, 5,250 to 10,500 RE/day (17,500 to 35,000 IU/day) for 10 days.

**Infants to age 1 year.** 1,500 to 3,000 RE/day (5,000 to 10,000 IU/day) for 10 days; for severe deficiency, 2,250 to 4,500 RE/day (7,500 to 15,000 IU/day) for 10 days.

I.V. INFUSION

**Adults and children.** Dosage individualized as part of total parenteral nutrition solution, as prescribed.

### TO TREAT XEROPHTHALMIA

CAPSULES, ORAL SOLUTION, TABLETS

**Children age 1 and over.** 60,000 RE (200,000 IU) as a single dose. Dose repeated on day 2 and again in 4 wk.

**Children ages 6 months to 1 year.** 30,000 RE (100,000 IU) as a single dose. Dose repeated on day 2 and again in 4 wk.

### AS AN ADJUNCT TO TREAT MEASLES

CAPSULES, ORAL SOLUTION, TABLETS

**Children age 1 and over.** 60,000 RE (200,000 IU) as a single dose when measles are diagnosed.

**Children ages 6 months to 1 year.** 30,000 RE (100,000 IU) as a single dose when measles are diagnosed.

## PARENTERAL ADMINISTRATION GUIDELINES

- Be aware that anaphylaxis and death have occurred after I.V. administration of vitamin A; I.V. administration is restricted to special solutions, such as in total parenteral nutrition solution. Typically, parenteral administration of vitamin A is by I.M. injection.
- Take precautions to protect vitamin A solution from exposure to light because it's light sensitive.

### TO TREAT VITAMIN B<sub>1</sub> DEFICIENCY (BERIBERI)

ELIXIR, TABLETS

**Adults.** 5 to 10 mg t.i.d.

**Children and infants.** 10 mg/day.

I.V. OR I.M. INJECTION

**Adults.** *Initial:* 5 to 100 mg every 8 hr, switched to P.O. vitamin B<sub>1</sub> therapy as soon as possible and continued for total of 1 mo.

- Be aware that I.V. administration of vitamin B<sub>1</sub> has caused severe and life-threatening reactions, especially with repeat administration. Monitor patient closely for angioedema, GI bleeding, respiratory distress, throat tightness, urticaria, vascular collapse, and weakness during and after administration.

GENERIC AND TRADE NAMES	RECOMMENDED DAILY INTAKE
<b>vitamin B<sub>1</sub></b> ( <i>continued</i> )	<p><b>Children ages 7 to 10.</b> 1 mg/day. (0.8 to 1 mg/day [CAN].)</p> <p><b>Children ages 4 to 7.</b> 0.9 mg/day. (0.7 mg/day [CAN].)</p> <p><b>Children ages 1 to 4.</b> 0.3 to 0.7 mg/day. (0.3 to 0.6 mg/day [CAN].)</p>
<p><b>vitamin B<sub>3</sub> (niacin)</b>  Endur-Acin, Nia-Bid, Niac, Niacels,  Niacor, Nico-400, Nicobid Tempules,  Nicolar, Nicotinex Elixir, Novo-Niacin  (CAN), Slo-Niacin</p>	<p><b>Adult men and boys age 11 and over.</b> 15 to 20 mg/day. (14 to 23 mg/day [CAN].)</p> <p><b>Adult women and girls age 11 and over.</b> 13 to 15 mg/day. (14 to 16 mg/day [CAN].)</p> <p><b>Pregnant women.</b> 17 mg/day. (14 to 16 mg/day [CAN].)</p> <p><b>Breastfeeding women.</b> 20 mg/day. (14 to 16 mg/day [CAN].)</p> <p><b>Children ages 7 to 11.</b> 13 mg/day. (14 to 18 mg/day [CAN].)</p> <p><b>Children ages 4 to 7.</b> 12 mg/day. (13 mg/day [CAN].)</p> <p><b>Neonates and children to age 4.</b> 5 to 9 mg/day. (4 to 9 mg/day [CAN].)</p>
<p><b>vitamin B<sub>6</sub> (pyridoxine hydrochloride)</b>  Beesix, Doxine, Nestrex, Pyri, Rodex,  Vita-bee 6</p>	<p><b>Adult men and boys age 11 and over.</b> 1.7 to 2 mg/day.</p> <p><b>Adult women and girls age 11 and over.</b> 1.4 to 1.6 mg/day.</p> <p><b>Pregnant women.</b> 2.2 mg/day.</p> <p><b>Breastfeeding women.</b> 2.1 mg/day.</p> <p><b>Children ages 7 to 10.</b> 1.4 mg/day.</p> <p><b>Children ages 4 to 6.</b> 1.1 mg/day.</p> <p><b>Neonates and children to age 3.</b> 0.3 to 1 mg/day.</p>

## OTHER INDICATIONS AND DOSAGES

### TO TREAT WERNICKE'S ENCEPHALOPATHY

I.V. OR I.M. INJECTION

**Adults.** *Initial:* 100 mg I.V. *Maintenance:* 50 to 100 mg I.V. or I.M. daily until normal recommended daily intake is achieved.

## PARENTERAL ADMINISTRATION GUIDELINES

- Rotate sites for I.M. administration of vitamin B<sub>1</sub> to help prevent induration and tenderness that may occur following administration.
- Be aware that I.M. administration may be painful; use the Z-track method of administration.
- Know that because of incompatibilities, parenteral vitamin B<sub>1</sub> shouldn't be added to alkaline or neutral solutions; also, don't mix it with oxidizing and reducing agents, including barbiturates, carbonates, citrates, and copper.
- Take precautions to protect vitamin B<sub>1</sub> solution from exposure to light because it's light sensitive.

### TO TREAT VITAMIN B<sub>3</sub> DEFICIENCY

E.R. CAPSULES, E.R. TABLETS, ORAL SOLUTION, TABLETS

**Adults and children age 11 and over.** Dosage individualized based on severity of deficiency, as prescribed. *Maximum:* 6 g/day.

I.V. INJECTION

**Adults and children age 11 and over.** 25 to 100 mg at least twice daily.

**Children to age 11.** Up to 300 mg daily

I.M. INJECTION

**Adults and children age 11 and over.** 50 to 100 mg at least 5 times/day.

**Children to age 11.** Dosage individualized based on severity of deficiency.

### TO TREAT HYPERLIPIDEMIA (NIAICIN ONLY)

E.R. CAPSULES, E.R. TABLETS, ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 1,000 mg t.i.d. Dosage increased by 500 mg/day every 2 to 4 wk, as needed. *Maintenance:* 1 to 2 g t.i.d. *Maximum:* 6 g/day.

**DOSAGE ADJUSTMENT** To reduce or prevent facial flushing, initial dosage reduced to 100 mg/day (tab) or 500 mg/day (E.R. tab), and then gradually increased to 3 to 4 g/day.

- Be aware that I.V. administration of vitamin B<sub>3</sub> may cause CNS or CV adverse reactions, such as arrhythmias, dizziness, headache, peripheral vasodilation, and syncope. Rate of I.V. administration shouldn't exceed 2 mg/min, regardless of method of I.V. administration.
- Know that vitamin B<sub>3</sub> must be diluted for I.V. use. For direct injection, dilute to 2 mg/ml; for intermittent or continuous infusion, dilute dose in 500 ml of normal saline or other compatible solution.
- Give I.M. injection following routine I.M. administration guidelines. Vitamin B<sub>3</sub> doesn't need to be diluted for I.M. injection.
- Be aware that parenteral administration shouldn't be used to treat hyperlipidemia.

### TO TREAT VITAMIN B<sub>6</sub> DEFICIENCY

E.R. CAPSULES, TABLETS

**Adults and children.** Dosage individualized based on severity of deficiency, as prescribed.

E.R. TABLETS

**Adults.** Dosage individualized based on severity of deficiency, as prescribed.

I.V. INFUSION

**Adults and children.** Dosage individualized as part of total parenteral nutrition.

- Be aware that I.M. or SubQ administration of vitamin B<sub>6</sub> may cause injection-site burning or stinging. Before giving injection, alert patient that this adverse effect may occur.
- Know that I.V. administration is given as part of a multivitamin solution; follow the guidelines for administering an I.V. multivitamin solution as recommended for the product being used.

GENERIC AND TRADE NAMES	RECOMMENDED DAILY INTAKE
<b>vitamin B<sub>6</sub></b> ( <i>continued</i> )	<p><b>Children ages 7 to 10.</b> 1.4 mg/day.</p> <p><b>Children ages 4 to 6.</b> 1.1 mg/day.</p> <p><b>Neonates and children to age 3.</b> 0.3 to 1 mg/day.</p> <p><b>Adult men and boys age 11 and over.</b> 1.7 to 2 mg/day.</p> <p><b>Adult women and girls age 11 and over.</b> 1.4 to 1.6 mg/day.</p> <p><b>Pregnant women.</b> 2.2 mg/day.</p> <p><b>Breastfeeding women.</b> 2.1 mg/day.</p>
<b>vitamin B<sub>9</sub> (folic acid)</b> Apo-Folic (CAN), Folvite, Novo-Folacid (CAN)	<p><b>Adult men and boys age 11 and over.</b> 150 to 400 mcg/day. (150 to 220 mcg/day [CAN].)</p> <p><b>Adult women and girls age 11 and over.</b> 150 to 400 mcg/day. (145 to 190 mcg/day [CAN].)</p> <p><b>Pregnant women.</b> 400 to 800 mcg/day. (445 to 475 mcg/day [CAN].)</p> <p><b>Breastfeeding women.</b> 260 to 800 mcg/day. (245 to 275 mcg/day [CAN].)</p> <p><b>Children ages 7 to 11.</b> 100 to 400 mcg/day. (125 to 180 mcg/day [CAN].)</p> <p><b>Children ages 4 to 7.</b> 75 to 400 mcg/day. (90 mcg/day [CAN].)</p> <p><b>Neonates and children to age 4.</b> 25 mcg/day. (50 to 80 mcg/day [CAN].)</p>
<b>vitamin B<sub>12</sub></b> (cyanocobalamin, hydroxycobalamin)	<p><b>Adults age 19 and over.</b> 2.4 mcg/day.</p> <p><b>Pregnant women.</b> 2.6 mcg/day.</p> <p><b>Breastfeeding women.</b> 2.8 mcg/day.</p> <p><b>Adolescents ages 14 to 19.</b> 2.4 mcg/day.</p> <p><b>Children ages 9 to 14.</b> 1.8 mcg/day.</p> <p><b>Children ages 4 to 9.</b> 1.2 mcg/day.</p> <p><b>Children ages 1 to 4.</b> 0.9 mcg/day.</p> <p><b>Infants ages 6 to 12 months.</b> 0.4 mcg/day.</p> <p><b>Neonates and infants to 6 months.</b> 0.5 mcg/day.</p>

OTHER INDICATIONS AND DOSAGES	PARENTERAL ADMINISTRATION GUIDELINES
<p><b>TO TREAT PYRIDOXINE DEPENDENCY SYNDROME</b>  I.V. OR I.M. INJECTION  <b>Adults and children age 11 and over.</b> 30 to 600 mg daily.  <b>Infants with seizures.</b> <i>Initial:</i> 10 to 100 mg, then individualized based on severity of deficiency, as prescribed.  <b>TO TREAT DRUG-INDUCED PYRIDOXINE DEFICIENCY</b>  I.V. OR I.M. INJECTION  <b>Adults and children age 11 and over.</b> 50 to 200 mg/day for 3 wk, then 25 to 100 mg/day, as needed.</p>	<ul style="list-style-type: none"> <li>• Know that vitamin B<sub>6</sub> may increase AST (SGOT) levels. Be aware that at least one manufacturer warns against I.V. administration of vitamin B<sub>6</sub> to patients with heart disease.</li> <li>• Take precautions to protect vitamin B<sub>6</sub> solution from exposure to light because it's light sensitive.</li> </ul>
<p><b>TO TREAT VITAMIN B<sub>9</sub> DEFICIENCY</b>  TABLETS  <b>Adults and children.</b> Dosage individualized based on severity of deficiency, as prescribed.  I.V. INFUSION, I.M. OR SUBCUTANEOUS INJECTION  <b>Adults and children.</b> 0.25 to 1 mg daily until hematologic response occurs.</p>	<ul style="list-style-type: none"> <li>• Be aware that some vitamin B<sub>9</sub> solutions contain benzyl alcohol. Don't administer these solutions to neonates or immature infants because of a risk of fatal toxic syndrome, which may include circulatory, CNS, renal, and respiratory impairment and metabolic acidosis.</li> <li>• Know that unless ordered otherwise, you should dilute 5 mg/ml of vitamin B<sub>9</sub> with 49 ml of sterile water for injection to provide a solution containing 0.1 mg of vitamin/ml.</li> <li>• Know that parenteral administration may cause anaphylaxis. Parenteral administration should be used only in patients with severe vitamin deficiency or in those with severely impaired GI absorption.</li> <li>• Be aware that SubQ administration should be injected deep.</li> <li>• Take precautions to protect vitamin B<sub>9</sub> solution from exposure to light because it's light sensitive.</li> </ul>
<p><b>TO TREAT VITAMIN B<sub>12</sub> DEFICIENCY</b>  <i>Caused by nutritional intake imbalance (not for use to treat pernicious anemia) lozenges, tablets</i>  <b>Adults and children.</b> Dosage individualized based on severity of deficiency, as prescribed.  <i>Caused by pernicious anemia; malabsorption disorders (tropical or nontropical sprue, partial or total gastrectomy, regional enteritis, gastroenterostomy, ileal resection); or malignancies, granulomas, strictures, or anastomoses involving the ileum.</i>  SUBCUTANEOUS INJECTION (CYANOCOBALAMIN)  <b>Adults.</b> <i>Initial:</i> 30 mcg daily for 5 to 10 days, then switched to I.M. administration for maintenance therapy.</p>	<ul style="list-style-type: none"> <li>• Be aware that parenteral vitamin B<sub>12</sub> solution is incompatible with many drugs, including ascorbic acid, chlorpromazine hydrochloride, dextrose, heavy metals, phytonadione, prochlorperazine edisylate, and warfarin sodium. Also know that alkaline or strongly acidic solutions and oxidizing or reducing agents are also incompatible with vitamin B<sub>12</sub> solution. Do not administer vitamin with other drugs.</li> <li>• Know that both cyanocobalamin and hydroxycobalamin may be administered by I.M. injection, but only cyanocobalamin may be administered as a SubQ injection. Be alert to which form is being administered to ensure correct route of administration.</li> </ul>

GENERIC AND TRADE NAMES	RECOMMENDED DAILY INTAKE
<b>vitamin B<sub>12</sub></b> ( <i>continued</i> )	<p><b>Children ages 7 to 10.</b> 1 mg/day. (0.8 to 1 mg/day [CAN].)</p> <p><b>Children ages 4 to 7.</b> 0.9 mg/day. (0.7 mg/day [CAN].)</p> <p><b>Children ages 1 to 4.</b> 0.3 to 0.7 mg/day. (0.3 to 0.6 mg/day [CAN].)</p>
<p><b>vitamin C (ascorbic acid)</b>            Ascorbic Acid, Cecon Drops,            Cenolate, Cevi-Bid, Vicks Vitamin C Drops</p>	<p><b>Adult men.</b> 90 mg/day.  <b>Adult women.</b> 75 mg/day.  <b>Pregnant women age 19 and over.</b> 85 mg/day.  <b>Breastfeeding women age 19 and over.</b> 120 mg/day.  <b>Adolescent boys ages 14 to 19.</b> 75 mg/day.  <b>Adolescent girls ages 14 to 19.</b> 65 mg/day.  <b>Pregnant girls ages 14 to 19.</b> 80 mg/day.  <b>Breastfeeding girls ages 14 to 19.</b> 115 mg/day.  <b>Children ages 9 to 14.</b> 45 mg/day.  <b>Children ages 4 to 9.</b> 25 mg/day.  <b>Children ages 1 to 4.</b> 15 mg/day.  <b>Infants ages 7 to 12 months.</b> 50 mg/day.  <b>Neonates and infants to age 7 months.</b> 40 mg/day.  <b>DOSAGE ADJUSTMENT</b> Recommended daily intake for people who smoke is 100 mg/day because of an increased utilization of vitamin C. Recommended daily intake should be increased to promote wound healing and for those with a chronic illness, fever, hemovascular disorder, or infection; the amount of vitamin C increase depends on the severity of the underlying condition.</p>

OTHER INDICATIONS AND DOSAGES	PARENTERAL ADMINISTRATION GUIDELINES
<p><b>Children.</b> <i>Initial:</i> 1,000 to 5,000 mcg given in single daily doses of 100 mcg over 2 or more wk. <i>Maintenance:</i> 60 or more mcg/mo.</p> <p>I.M. INJECTION (CYANOCOBALAMIN OR HYDROXYCOBALAMIN)</p> <p><b>Adults.</b> <i>Initial:</i> 30 mcg daily for 5 to 10 days. <i>Maintenance:</i> 100 to 200 mcg every mo.</p> <p><b>Children.</b> <i>Initial:</i> 1,000 to 5,000 mcg, given in single daily doses of 100 mcg over 2 or more wk. <i>Maintenance:</i> 60 or more mcg/mo.</p> <p><b>DOSAGE ADJUSTMENT</b> Dosage adjusted, as needed, to maintain normal hematologic morphology and an erythrocyte count greater than 4.5 million/mm.</p> <p><b>Adults.</b> <i>Initial.</i> 1 mg/wk for 3 wk. <i>Maintenance:</i> 250 mcg/mo.</p> <p><b>TO TREAT FAMILIAL SELECTIVE B<sub>12</sub> MALABSORPTION</b></p> <p>I.M. INJECTION (CYANOCOBALAMIN)</p> <p><b>TO TREAT HEREDITARY DEFICIENCY OF TRANSCOBALAMIN II</b></p> <p>I.M. INJECTION (CYANOCOBALAMIN)</p> <p><b>Adults.</b> 1 to 2 mg/wk.</p>	<ul style="list-style-type: none"> <li>• Be aware that SubQ administration of cyanocobalamin should be injected deeply.</li> <li>• Know that vitamin B<sub>12</sub> is excreted more rapidly after I.V. injection; I.V. administration isn't recommended.</li> <li>• Take precautions to protect vitamin B<sub>12</sub> solution from exposure to light because it's light sensitive.</li> </ul>
<p><b>TO TREAT VITAMIN C DEFICIENCY (SCURVY)</b></p> <p>E.R. CAPSULES; LOZENGES; ORAL SOLUTION;</p> <p>E.R. TABLETS; TABLETS; SUBCUTANEOUS, I.M., OR I.V. INJECTION</p> <p><b>Adults.</b> 100 to 250 mg once or twice daily until skeletal changes and signs and symptoms of hemorrhagic disorder are reversed (usually within 2 to 21 days).</p> <p>ORAL SOLUTION; TABLETS; SUBCUTANEOUS, I.M., OR I.V. INJECTION</p> <p><b>Infants and children.</b> 100 to 300 mg/day in divided doses until skeletal changes and signs and symptoms of hemorrhagic disorder are reversed (usually within days).</p>	<ul style="list-style-type: none"> <li>• Be aware that I.M. injection is the preferred parenteral route for administering vitamin C, although it may be administered I.V. or SubQ when necessary.</li> <li>• Rotate sites for I.M. and SubQ administration to help prevent transient mild soreness that may occur following administration. Inform patient that this adverse effect may occur.</li> <li>• Avoid rapid administration, if giving I.V. vitamin C, to prevent dizziness or faintness.</li> <li>• Administer vitamin C solution by itself because it's incompatible with many drugs.</li> <li>• Be aware that vitamin C solution rapidly oxidizes in air and in alkaline solutions. Take precautions to protect vitamin solution from exposure to air and light.</li> <li>• Open vitamin C ampules carefully because increased pressure may develop after prolonged storage.</li> </ul>

GENERIC AND TRADE NAMES	RECOMMENDED DAILY INTAKE
<b>vitamin D<sub>2</sub> (ergocalciferol)</b> Calciferol, Calciferol Drops, Drisdol, Drisdol Drops, Ostoforte (CAN), Radiostol Forte (CAN)	<p><b>Adults and children ages 11 and over.</b> 200 to 400 IU/day. (100 to 200 IU/day [CAN].)</p> <p><b>Pregnant and breastfeeding women.</b> 400 IU/day. (200 to 300 IU/day [CAN].)</p> <p><b>Children ages 7 to 11.</b> 400 IU/day. (100 to 200 IU/day [CAN].)</p> <p><b>Children ages 4 to 7.</b> 400 IU/day. (200 IU/day [CAN].)</p> <p><b>Neonates and children to age 4.</b> 300 to 400 IU/day. (200 to 400 IU/day [CAN].)</p>
<b>vitamin E (alpha tocopherol)</b> Amino-Opti-E, Aquasol E, E-Complex 600, E-Vitamin succinate, Liqui-E, Pheryl E, Vita-Plus E, Webber Vitamin E (CAN)	<p><b>Adult men and adolescent boys.</b> 16.7 IU/day. (10 to 16.7 IU/day [CAN].)</p> <p><b>Adult women and adolescent girls.</b> 13 IU/day. (8.3 to 11.7 IU/day [CAN].)</p> <p><b>Pregnant women.</b> 16.7 IU/day. (13 to 15 IU/day [CAN].)</p> <p><b>Breastfeeding women.</b> 18 to 20 IU/day. (15 to 16.7 IU/day [CAN].)</p> <p><b>Children ages 7 to 10.</b> 11.7 IU/day. (10 to 13 IU/day [CAN].)</p> <p><b>Children ages 4 to 7.</b> 11.7 IU/day. (8.3 IU/day [CAN].)</p> <p><b>Infants and children to age 4.</b> 5 to 10 IU/day. (5 to 6.7 IU/day [CAN].)</p>

OTHER INDICATIONS AND DOSAGES	PARENTERAL ADMINISTRATION GUIDELINES
<p><b>TO TREAT VITAMIN D<sub>2</sub> DEFICIENCY</b> CAPSULES, ORAL SOLUTION, TABLETS <b>Adults and children.</b> Dosage individualized based on severity of deficiency, as prescribed.</p> <p><b>TO TREAT VITAMIN D-RESISTANT RICKETS</b> CAPSULES, ORAL SOLUTION, TABLETS <b>Adults.</b> 12,000 to 150,000 IU units daily</p> <p><b>TO TREAT VITAMIN D-DEPENDENT RICKETS</b> CAPSULES, ORAL SOLUTION, TABLETS <b>Adults.</b> 10,000 to 60,000 IU daily. <i>Maximum:</i> 150,000 IU daily. <b>Children.</b> 3,000 to 10,000 IU daily. <i>Maximum:</i> 50,000 IU daily.</p> <p><b>TO TREAT OSTEOMALACIA CAUSED BY LONG-TERM ANTICONVULSANT USE</b> CAPSULES, ORAL SOLUTION, TABLETS <b>Adults.</b> 1,000 to 4,000 IU daily. <b>Children.</b> 1,000 IU daily.</p> <p><b>TO TREAT FAMILIAL HYPOPHOSPHATEMIA</b> CAPSULES <b>Adults.</b> 50,000 to 100,000 IU daily.</p> <p><b>TO TREAT HYPOPARATHYROIDISM</b> CAPSULES <b>Adults.</b> 50,000 to 150,000 IU daily. <b>Children.</b> 50,000 to 200,000 IU daily.</p> <p><b>TO TREAT INTESTINAL MALABSORPTION</b> I.M. INJECTION <b>Adults and children.</b> 10,000 IU daily.</p>	<ul style="list-style-type: none"> <li>• Be aware that vitamin D<sub>2</sub> is usually given orally. However, I.M. injection may be required for patients with biliary, GI, or liver disease associated with malabsorption of vitamin D analogues.</li> <li>• Take precautions to protect parenteral vitamin D<sub>2</sub> solution from exposure to light because light causes it to decompose.</li> </ul>
<p><b>TO TREAT VITAMIN E DEFICIENCY</b> CAPSULES (ADULTS ONLY), ORAL SOLUTION, TABLETS <b>Adults and children.</b> Dosage individualized based on severity of deficiency, as prescribed.</p>	<p>Know that vitamin E isn't administered parenterally.</p>

GENERIC AND TRADE NAMES	RECOMMENDED DAILY INTAKE
<b>vitamin K<sub>1</sub> (phytonadione)</b> AquaMEPHYTON, Mephyton	<p><i>Recommended daily intake hasn't been established for vitamin K<sub>1</sub>. However, adequate intake is suggested as follows:</i></p> <p><b>Adult men age 19 and over.</b> 120 mcg/day.</p> <p><b>Adult women age 19 and over, pregnant and breast-feeding women.</b> 90 mcg/day.</p> <p><b>Adolescents ages 14 to 19.</b> 75 mcg/day.</p> <p><b>Children ages 9 to 14.</b> 60 mcg/day.</p> <p><b>Children ages 4 to 9.</b> 55 mcg/day.</p> <p><b>Children ages 1 to 4.</b> 30 mcg/day.</p> <p><b>Infants ages 7 to 12 months.</b> 2.5 mcg/day.</p> <p><b>Neonates and infants to age 7 months.</b> 2 mcg/day.</p>

## OTHER INDICATIONS AND DOSAGES

### TO PREVENT HYPOPROTHROMBINEMIA DURING PROLONGED USE OF TOTAL PARENTERAL NUTRITION

I.M. INJECTION

**Adults.** 5 to 10 mg/wk.

**Children.** 2 to 5 mg/wk.

### TO PREVENT HYPOPROTHROMBINEMIA IN INFANTS WITH DIETS DEFICIENT IN VITAMIN K (LESS THAN 100 MCG/L)

I.M. INJECTION

**Infants.** 1 mg/mo.

### TO TREAT ANTICOAGULANT-INDUCED HYPOPROTHROMBINEMIA

TABLETS, I.M. OR SUBCUTANEOUS INJECTION

**Adults.** 2.5 to 25 mg, repeated 12 to 48 hr after P.O. dose or 6 to 8 hr after SubQ or I.M. dose, as prescribed.

*Maximum:* 50 mg/dose.

**Children.** 2.5 to 10 mg SubQ or I.M., repeated in 6 to 8 hr, as prescribed.

**Infants.** 1 to 2 mg SubQ or I.M., repeated in 4 to 8 hr, as prescribed.

### TO TREAT HYPOPROTHROMBINEMIA FROM OTHER CAUSES

TABLETS, I.M. OR SUBCUTANEOUS INJECTION

**Adults.** 2 to 25 mg. *Usual:* 25 mg. *Maximum:* 50 mg/dose.

**Children.** 5 to 10 mg SubQ or I.M.

**Infants.** 2 mg SubQ or I.M.

### TO PREVENT HEMORRHAGIC DISEASE IN NEONATES

I.M. OR SUBCUTANEOUS INJECTION

**Neonates.** 0.5 to 1 mg within 1 hr after birth, repeated in 6 to 8 hr, as prescribed.

### TO TREAT HEMORRHAGIC DISEASE IN NEONATES

I.M. OR SUBCUTANEOUS INJECTION

**Neonates.** 1 mg (or higher dose if mother took an oral anticoagulant or anticonvulsant during pregnancy).

## PARENTERAL ADMINISTRATION GUIDELINES

- Be aware that severe adverse reactions, including anaphylaxis, cardiac and respiratory arrest, hypersensitivity, and shock, may occur during or immediately after I.M. or I.V. administration of vitamin K<sub>1</sub>, even if it's diluted to avoid rapid infusion. Administer vitamin by SubQ route whenever possible.
- Know that if vitamin K<sub>1</sub> must be administered I.V., you should not exceed rate of 1 mg/min, as prescribed.
- Be aware that some vitamin K<sub>1</sub> solutions contain benzyl alcohol. Don't administer these solutions to neonates or immature infants because of a risk of fatal toxic syndrome, which may include circulatory, CNS, renal, and respiratory impairment and metabolic acidosis.
- Take precautions to protect vitamin K<sub>1</sub> solution from exposure to light because it's light sensitive.

# Interferons

Interferons are classified as biological response modifiers or antineoplastics. They fall into three major categories—alpha, beta, and gamma—which are described below.

The table on the following pages lists the trade names, indications, usual adult dosages, adverse reactions, and nursing considerations for these interferons.

## Interferon alpha

Highly purified proteins produced by a recombinant DNA process, drugs in this category exhibit antiviral and antitumor activity. Antiviral activity depends on their inhibition of viral protein synthesis. Antitumor activity results from their ability to exert a cytostatic effect, reducing the rate of cell proliferation by delaying RNA and protein production. This delay induces cells to enter a resting stage. These drugs also increase the activity of human natural killer (NK) cells, which have the ability to lyse certain tumor cells and normal targets. They also selectively increase the number of cytotoxic T-cells, thereby affecting tumor growth. Phagocytic activity of macrophages also is increased.

## Interferon alfacon

This specific form of interferon is produced by fermentation of genetically engineered *Escherichia coli*. It's structurally and functionally related to interferon beta and has greater biological activity than other interferon alfas.

## Interferon beta

Produced by fibroblasts and epithelial cells, drugs in this category neutralize the activity of endogenous interferon gamma (IFNG), the substance believed to be responsible for triggering the autoimmune process that leads to multiple sclerosis. In multiple sclerosis, an initial viral infection may stimulate IFNG production by T cells. Then IFNG induces macrophages to produce proteinases that degrade the myelin sheath around the nerves and spinal cord. Cytotoxic T cells then move to the site of inflammation, recognizing antigens as receptor sites, where they attack the tissue affected by IFNG, resulting in progressive neurologic dysfunction. Interferon beta drugs interfere with IFNG production by

lymphocytes and the mRNA transcription caused by IFNG. As a result, cytotoxic T cells can't locate receptor sites and cause further damage in the CNS.

## **Interferon gamma**

Produced from genetically engineered *E. coli*, this type of interferon is chemically and therapeutically distinct from interferon alpha. Drugs in this category have potent phagocyte-activating properties. By enhancing oxidative metabolism, they produce toxic oxygen metabolites in phagocytes, which permits more efficient killing of certain fungi, bacteria, and protozoal microbes. Enhanced antibody-dependent cellular cytotoxicity and NK-cell activity reduce the risk of developing a serious infection in patients with chronic disease. These drugs also stimulate production of cytokines, such as interleukin-1-beta, and regulate the immune system by suppressing the IgE level and inhibiting collagen production.

GENERIC AND TRADE NAMES	INDICATIONS AND USUAL ADULT DOSAGES
<b>Interferon alpha drugs</b>	
<b>interferon alfa-n3</b> Alferon N	<i>To treat condyloma acuminatum:</i> 250,000 international units intral- esionally at base of wart 2 times/wk for up to 8 wk.
<b>peginterferon alfa-2a</b> PEGASYS	<i>As monotherapy to treat patients with chronic hepatitis C who have compensated liver disease and contraindications or significant intoler- ance to other hepatitis C virus antiviral drugs; as adjunct to treat patients with chronic hepatitis C and compensated liver disease in combination with other antiviral drugs; to treat patients with chronic hepatitis B who have compensated liver disease and evidence of viral replication and liver inflammation:</i> 180 mcg/wk SubQ for individualized length of time for chronic hepatitis C and 48 wk for chronic hepatitis B.
<b>peginterferon alfa-2b</b> PEG-Intron Sylatron	<i>As adjunct to treat patients with chronic hepatitis C who have compen- sated liver disease and have never received an interferon alpha:</i> 180 mcg/wk SubQ for 48 wk.  <i>To treat patients with chronic hepatitis C:</i> 1 mcg/kg/wk (PEG-Intron) SubQ every wk on the same day of the wk for 1 yr.  <i>As adjunct to treat patients with chronic hepatitis C in combination with ribavirin:</i> 1.5 mcg/kg (PEG-Intron) SubQ every wk on the same day of the wk for 48 wk for genotype 1 and 24 wk for genotype 2 or 3.  <i>As adjunct treatment of melanoma with microscopic or gross nodal involve- ment within 84 days of definitive surgical resection:</i> 6 mcg/kg/wk (Sylatron) SubQ for 8 doses followed by 3 mcg/kg/wk (Sylatron) SubQ for up to 5 yr.  <i>To treat hairy cell leukemia:</i> 2 million international units/m <sup>2</sup> I.M. or SubQ 3 times/wk for up to 6 mo.
<b>recombinant interferon alfa-2b</b> Intron A	<i>To treat condyloma acuminatum:</i> 1 million international units (using only the 10-million units/ml strength) intralesionally at base of wart (up to 5 warts/course) 3 times/wk on alternate days for 3 wk. If response is inad- equate 12 to 16 wk after initial treatment, repeat course, as prescribed.

ADVERSE REACTIONS	NURSING CONSIDERATIONS
<p><b>CNS:</b> Depression, dizziness, fatigue, headache, <b>homicidal or suicidal ideation</b>, psychosis, peripheral neuropathy, <b>seizures</b>, vertigo</p> <p><b>CV:</b> Hypertriglyceridemia, hypertension, <b>hypotension</b>, palpitations</p> <p><b>EENT:</b> Dry mouth, hearing loss</p> <p><b>GI:</b> Anorexia, diarrhea, <b>hepato-toxicity</b>, nausea, vomiting</p> <p><b>GU:</b> <b>Renal failure</b></p> <p><b>HEME:</b> Anemia, <b>leukopenia</b>, <b>pure red cell aplasia</b>, <b>thrombocytopenia</b>, <b>thrombotic thrombocytopenic purpura</b></p> <p><b>MS:</b> Myositis, <b>rhabdomyolysis</b></p> <p><b>RESP:</b> <b>Pulmonary fibrosis</b></p> <p><b>SKIN:</b> Alopecia, rash, <b>Stevens–Johnson syndrome</b>, <b>toxic epidermal necrolysis</b>, urticaria</p> <p><b>Other:</b> <b>Anaphylaxis</b>, <b>angioedema</b>, bacterial infections, flu-like symptoms, liver or renal graft rejection, <b>sepsis</b>, systemic lupus erythematosus</p>	<ul style="list-style-type: none"> <li>• Use interferon alpha drugs cautiously in patients with renal impairment and in elderly patients.</li> <li>• Be aware that cross-sensitivity may occur among interferon alpha drugs.</li> <li>• Be aware that interferon alpha drugs aren't interchangeable.</li> <li>• Be aware that patients who are sensitive to mouse immunoglobulin also may be sensitive to recombinant interferon alfa-2a.</li> <li>• Ensure that patient is well hydrated, if not contraindicated, at the start of and throughout therapy to reduce the risk of hypotension.</li> <li>• Reconstitute by adding 3 ml of diluent provided by manufacturer and swirling gently to dissolve.</li> <li>• Be aware that reconstitution of peginterferon alfa-2a and interferon alfa-n3 is not necessary.</li> <li>• Don't shake vial.</li> <li>• Be aware that cross-sensitivity with interferon alfa-n3 to egg protein, mouse immunoglobulin, or neomycin may occur.</li> </ul> <p><b>WARNING</b> Know that because interferon alpha drugs may cause or aggravate fatal or life-threatening autoimmune, ischemic, infectious, or neuropsychiatric disorders, patient should be monitored periodically with clinical and laboratory evaluations; expect drug to be discontinued if he develops severe or worsening signs and symptoms of these conditions.</p>

GENERIC AND TRADE NAMES	INDICATIONS AND USUAL ADULT DOSAGES
<b>Interferon alpha drugs</b>	
	<p><i>To treat AIDS-related Kaposi's sarcoma:</i> 30 million international units/m<sup>2</sup> (using 50 million international units/ml) I.M. or SubQ 3 times/wk.</p> <p><i>To treat chronic hepatitis B:</i> 5 million international units/day or 10 million international units 3 times/wk I.M. or SubQ for 16 wk.</p> <p><i>To treat chronic hepatitis C:</i> 3 million international units I.M. or SubQ 3 times/wk.</p> <p><i>To treat malignant melanoma:</i> 20 million international units/m<sup>2</sup> as I.V. infusion over 20 min for 5 consecutive days/wk for 4 wk, followed by 10 million international units/m<sup>2</sup> SubQ 3 times/wk for 48 wk.</p> <p><i>As adjunct to treat follicular lymphoma:</i> 5 million international units/m<sup>2</sup> 3 times/wk SubQ for up to 18 months.</p>
<b>Interferon alfacon-1 drugs</b>	
<b>interferon alfacon-1</b> Infergen	<p><i>To treat chronic hepatitis C in patients with compensated liver disease:</i> 9 mcg SubQ 3 times/wk, at intervals of at least 48 hr, for 24 wk. If inadequate response or relapse occurs, 15 mcg SubQ 3 times/wk, for up to 48 wk.</p> <p><i>As adjunct with ribavirin to treat chronic hepatitis C:</i> 15 mcg daily for up to 48 wk.</p>
<b>Interferon beta drugs</b>	
<b>interferon beta-1a</b> Avonex	<p><i>To treat relapsing forms of multiple sclerosis:</i> 30 mcg I.M. once/wk.</p>
Rebif	<p><i>To treat relapsing forms of multiple sclerosis: Initial:</i> 20% of maintenance dose 3 times/wk SubQ, and increased over 4-wk period to the targeted maintenance dose. <i>Maintenance:</i> 22 mcg or 44 mcg SubQ 3 times/wk.</p>
<b>interferon beta-1b</b> Betaseron, Extavia	<p><i>To treat relapsing forms of multiple sclerosis:</i> 0.0625 mg SubQ every other day for wk 1 and 2, increased to 0.125 mg SubQ every other day for wk 3 and 4, increased to 0.1875 mg SubQ every other day for wk 5 and 6, and increased to 0.25 mg SubQ every other day on wk 7 and thereafter.</p>
<b>peginterferon beta-1a</b> Plegridy	<p><i>To treat relapsing forms of multiple sclerosis:</i> 63 mcg on day 1, 94 mcg on day 15, and 125 mcg on day 29 and every 14 days thereafter.</p>

ADVERSE REACTIONS	NURSING CONSIDERATIONS
	<ul style="list-style-type: none"> <li>• Obtain CBC before and regularly during treatment, as ordered, because interferon alpha drugs may cause bone marrow suppression. Expect drug to be discontinued if patient develops severe decreases in neutrophil or platelet count.</li> <li>• Implement bleeding and infection-control measures, according to facility policy.</li> <li>• Be aware that cross-sensitivity may occur with <i>Escherichia coli</i>-derived products.</li> <li>• Discard vial if left at room temperature for more than 12 hours.</li> <li>• Implement bleeding and infection-control measures, according to facility policy.</li> <li>• Administer acetaminophen, as prescribed, to prevent or treat fever or headache.</li> </ul>

## Compatible Drugs in a Syringe

The table below lets you know at a glance whether particular drugs are compatible for at least 15 minutes when mixed together in a syringe for immediate administration. However, keep in mind that drugs listed as compatible when mixed in a syringe may not be compatible when prepared for other routes of administration. Drug combinations prepared for immediate administration usually require a more concentrated solution than those prepared for infusion.

**Key:** C = Compatible; I = Incompatible; n/a = Compatibility information not available, no recommendations can be given.

\* Compatible only with morphine doses of 1, 2, and 5 mg.

# Drug Formulas and Calculations

When giving drugs, you must be familiar with drug formulas and calculation methods to make sure your patient receives the prescribed drug in the correct dosage, strength, or flow rate. This appendix offers a quick review of ways to calculate the strength of a solution, drug dosages, and I.V. flow rates.

## Calculating the Strength of a Solution

Most solutions are prepared in the required strength by the pharmacy or medical supply source.

But sometimes only a concentrated form is available, and you'll need to dilute the solution or solid to administer the prescribed strength.

When a solid form of a drug is used to prepare a solution, the drug must be completely dissolved. Solid drug forms, such as tablets, crystals, and powders, are considered 100% strength. (An exception to this is boric acid, which is only 5% at full strength.) The final diluted solution is stated in terms of liquid measurement. To prepare a solution, you'll need to add the prescribed solid or liquid form of the drug (the solute) to the prescribed amount of diluent (the solvent). Two of the most common clinical diluents are normal saline solution and sterile water.

You can use two formulas to calculate the strength of a solution, as shown in the examples below.

### Method 1: Calculating percentage and volume

Use the following formula:

$$\frac{\text{Weaker solution}}{\text{Stronger solution}} = \frac{\text{Solute}}{\text{Solvent}}$$

**Example:** You need to dilute a stock solution of 100% strength to a 5% solution.

How much solute will you need to add to obtain 500 ml of the 5% solution?

Calculate as follows:

$$\frac{5 (\%) \text{ (Weaker solution)}}{100 (\%) \text{ (Stronger solution)}} = \frac{X \text{ (g) (solute)}}{500 \text{ ml (solvent)}}$$

$$100 X = (500)(5) \text{ or } 2,500$$

$$X = 25 \text{ g}$$

**Answer:** You'll need to add 25 g of solute to each 500 ml of solvent to prepare a 5% solution.

## Method 2: Calculating percentage and volume

Use the following formula:

$$\frac{(\text{Desired strength})}{(\text{Available strength})} \times \text{Total amount of desired solution} = X \text{ (amount of undiluted drug needed to make solution)}$$

**Example:** You need to make 100 ml of a 20% solution, using an 80% solution.

How much of the 80% solution must you add to the sterile water to yield a final volume of 100 ml of a 20% solution?

Calculate as follows:

$$\frac{20 (\%)(\text{Desired strength})}{80 (\%)(\text{Available strength})} \times 100 \text{ ml (Total amount of desired solution)} = X$$

$$\frac{0.20}{0.80} = 0.25$$

$$0.25 \times 100 \text{ (ml)} = X$$

$$X = 25 \text{ ml of 80\% solution}$$

**Answer:** You'll need to add 25 ml of the 80% solution to the water to make a final volume of 100 ml of a 20% solution.

## Calculating Drug Dosages

You may be required to calculate drug dosages when you need to administer a drug that's available only in one measure, but prescribed in another. You should also be prepared to convert various units of measure, such as milligrams (mg) to grains (gr), and dry measurements to liquid. You can use three common methods of ratio and proportion to calculate drug dosages, as shown in the examples below.

### *CALCULATING ORAL DRUG DOSAGES*

**Example:** You need to give a patient 0.25 mg of digoxin, which comes only in 0.125-mg tablets. How many tablets will you need to give him to attain the proper dosage?

### **Method 1: Using labeled amount of drug**

In this method, true proportions between the drug label and the prescribed dose are used to determine ratio and proportion. The drug label, which states the amount of drug in one unit of measurement—in this case, 0.125 mg in each tablet of digoxin—is the first ratio, expressed as follows:

milligrams : tablets = milligrams : tablets

0.125 mg (amount of drug) : 1 tablet (unit of measure)

The prescribed dose—in this case, 0.25 mg—is the second ratio; it must be stated in the same order and units of measure as the first, as follows:

0.125 mg : 1 tablet = 0.25 mg : X (tablets)

Calculate as follows:

$$0.125 \times X = 0.25$$

$$X = \frac{0.25}{0.125}$$

$$X = 2$$

**Answer:** You'll need to give the patient 2 tablets of digoxin 0.125 mg.

Be sure to use critical thinking to assess whether your answer is correct. Because the amount of drug prescribed is greater than the amount of drug in one tablet, it's reasonable to expect the required number of tablets to be greater than one.

## Method 2: Using an established formula

To determine the correct number of digoxin tablets to give using this method, use the following formula:

$$\frac{\text{Prescribed dose}}{\text{Dose available}} \times \text{Quantity (unit of measure)} = X \text{ (unknown quantity to be given)}$$

Calculate as follows:

$$\frac{0.25 \text{ mg}}{0.125 \text{ mg}} \times 1 \text{ tablet} = X \text{ (number of 0.125-mg tablets)}$$

$$\frac{0.25}{0.125} = X$$

$$2 = X$$

**Answer:** You'll need to give the patient 2 tablets of digoxin 0.125 mg.

## Method 3: Calculating according to proportion size

This method uses the same components as method #1, but the ratio is based on proportions according to size. To determine the correct number of digoxin tablets to give using this method, use the following formula:

$$\frac{\text{Smaller}}{\text{Larger}} = \frac{\text{Smaller}}{\text{Larger}}$$

Substitute 0.125 into the smaller part and 0.25 into the greater part of the first ratio. Critical thinking leads us to believe that you'll need more than 1 tablet of the weaker 0.125-mg strength to equal the stronger 0.25 mg. Set up the proportion as follows:

$$\frac{0.125 \text{ mg}}{0.25 \text{ mg}} = \frac{1 \text{ (tablet)}}{X \text{ (tablets)}}$$

Calculate as follows:

$$0.125 X = 0.25$$

$$X = \frac{0.25}{0.125}$$

$$X = 2 \text{ tablets}$$

**Answer:** You'll need to give the patient 2 tablets of digoxin 0.125 mg.

### CALCULATING PARENTERAL DRUG DOSAGES

The same methods used for calculating oral drugs and solutions can be used for preparing parenteral injections.

**Example:** You need to administer a prescribed dose of 1 mg morphine sulfate from a unit-dose cartridge containing 4 mg/2 ml. How many milliliters will you need to give to equal the prescribed dose of 1 mg?

## Method 1: Using labeled amount of drug

Using the same ratio as for oral drugs, the drug label—in this case, 4 mg—is the first ratio, and the prescribed dose—in this case, 1 mg—is the second ratio, expressed as follows:

4 mg (the amount of drug) : 2 ml (the unit of measure)

Calculate as follows:

$$4 \text{ mg} : 2 \text{ ml} = 1 \text{ mg} : X \text{ ml}$$

$$4X = 2$$

$$X = \frac{2}{4}$$

$$X = 0.5 \text{ ml}$$

**Answer:** You'll need to give 0.5 ml of morphine sulfate to equal the prescribed dose of 1 mg.

## Method 2: Using an established formula

Use this formula:

$$\frac{\text{Prescribed dose}}{\text{Dose available}} \times \text{Quantity (unit of measure)} = X \text{ (unknown quantity to be given)}$$

Calculate as follows:

$$\frac{1 \text{ mg}}{4 \text{ mg}} \times 2 \text{ ml} = X \text{ (number of ml)}$$

$$\frac{2}{4} = 0.5$$

**Answer:** You'll need to give 0.5 ml of morphine sulfate to equal the prescribed dose of 1 mg.

### Method 3: Calculating according to proportion size

To determine the correct amount of morphine sulfate to give using this method, use the following formula:

$$\begin{aligned} \text{smaller} : \text{greater} &= \text{smaller} : \text{greater} \\ \text{milligrams} : \text{milligrams} &= \text{milliliters} : \text{milliliters} \end{aligned}$$

Critical thinking leads us to believe that 1 mg is less than 4 mg and that you'll need less than 2 ml to give 1 mg of the drug; therefore, 1 mg goes into the smaller part of the first ratio, and X goes into the smaller part of the second ratio. Set up the proportion as follows:

$$1 \text{ mg} : 4 \text{ mg} = X \text{ (ml)} : 2 \text{ ml}$$

$$4X = 2$$

$$X = \frac{2}{4}$$

$$X = 0.5$$

**Answer:** You'll need to give 0.5 ml of morphine sulfate to equal the prescribed dose of 1 mg.

## Calculating I.V. Flow Rates

When an I.V. solution is delivered by gravity, you must calculate the number of drops needed per minute for proper infusion. To calculate I.V. flow rates, you need to know three things:

- The drip factor—or the number of drops contained in 1 ml for the type of I.V. set you'll be using. This information is provided on the individual package label.
- The amount and type of fluid that you'll infuse as prescribed on the physician's order sheet
- The infusion duration time in minutes.

Once you've gathered this information, you can calculate the I.V. flow rate using the following equation:

$$\frac{\text{Total number of ml}}{\text{Total number of minutes}} \times \text{drip factor (gtt/ml)} = \text{flow rate (gtt/min)}$$

**Example 1:** If the physician prescribes 1,000 ml of D<sub>5</sub>W to infuse over 10 hours, and the drip rate for your administration set is 15 drops (gtt)/ml, calculate as follows:

$$\frac{1,000 \text{ ml}}{10 \text{ hours} \times 60 \text{ minutes}} \times 15 \text{ gtt/ml} = X \text{ gtt/minute}$$

$$\frac{1,000 \text{ ml}}{600 \text{ minutes}} \times 15 \text{ gtt/ml} = X \text{ gtt/minute}$$

$$1.67 \text{ ml/minute} \times 15 \text{ gtt/ml} = X \text{ gtt/minute}$$

$$25.05 \text{ gtt/minute} = X$$

**Answer:** To infuse, round off 25.05 to 25 gtt/minute or according to your institution's policy.

**Example 2:** If the physician prescribes 500 ml of half-normal (0.45%) saline solution to infuse over 2 hours, and the drip rate for your administration set delivers 10 gtt/ml, calculate as follows:

$$\frac{500 \text{ ml}}{2 \text{ hours} \times 60 \text{ minutes}} \times 10 \text{ gtt/ml} = X \text{ gtt/minute}$$

$$\frac{500 \text{ ml}}{120 \text{ minutes}} \times 10 \text{ gtt/ml} = X \text{ gtt/minute}$$

$$4.17 \text{ ml/minute} \times 10 \text{ gtt/ml} = X \text{ gtt/minute}$$

$$41.7 \text{ gtt/minute} = X$$

**Answer:** To infuse, round off 41.7 to 42 gtt/minute or according to your institution's policy.

*Note:* When preparing for I.V. administration using a controlled infusion device, the electronic flow-regulator will either count drops using an electronic eye or use a controlled pumping action to deliver the fluid in milliliters. Your final calculation will be based on the unit of measure used by the device: drops per minute or ml per hour.

# Weights and Equivalents

The following three tables show approximate equivalents among systems of measurement.

**Table 1 Liquid Equivalents Among Household, Apothecaries', and Metric Systems**

HOUSEHOLD	APOTHECARIES'	METRIC
1 teaspoon (tsp)	1 fluid dram	5 milliliters (ml)
1 tablespoon (tbs)	0.5 fluid oz	15 ml
2 tbs (1 ounce [oz])	1 fluid oz	30 ml
1 cupful	8 fluid oz	240 ml
1 pint	16 fluid oz	473 ml
1 quart (qt)	32 fluid oz	946 ml (1 liter)

**Table 2 Solid Equivalents Among Apothecaries' and Metric Systems**

APOTHECARIES'	METRIC
15 grains (gr)	1 gram (g) (1,000 milligrams [mg])
10 gr	0.6 g (600 mg)
7.5 gr	0.5 g (500 mg)
5 gr	0.3 g (300 mg)
3 gr	0.2 g (200 mg)
1.5 gr	0.1 g (100 mg)
1 gr	0.06 g (60 mg) or 0.065 g (65 mg)
0.75 gr	0.05 g (50 mg)
0.5 gr	0.03 g (30 mg)

<b>APOTHECARIES'</b>	<b>METRIC</b>
0.25 gr	0.015 g (15 mg)
1/60 gr	0.001 g (1 mg)
1/100 gr	0.6 mg
1/120 gr	0.5 mg
1/150 gr	0.4 mg

**Table 3 Solid Equivalents Among Avoirdupois, Apothecaries', and Metric Systems**

<b>AVOIRDUPOIS</b>	<b>APOTHECARIES'</b>	<b>METRIC</b>
1 gr	1 gr	0.065 g
15.4 gr	15 gr	1 g
1 ounce (oz)	480 gr	28.35 g
437.5 gr	1 oz	31 g
1 pound (lb)	1.33 lb	454 g
0.75 lb	1 lb	373 g
2.2 lb	2.7 lb	1 kg

## Equianalgesic Doses for Opioid Agonists

An equianalgesic dose of a synthetic opioid agonist is the dose that produces the same level of analgesia as 10 mg of I.M. or subQ morphine, the principal opioid obtained from opium poppies. If your patient is switched from one opioid to another, expect to use the equianalgesic dose to decrease the risk of adverse reactions while increasing the likelihood of adequate pain relief. The chart below compares equianalgesic doses (oral and parenteral) for adults and children who weigh 50 kg (110 lb) or more.

OPIOID	ORAL DOSE	PARENTERAL DOSE
codeine	200 mg (not recommended)	120 to 130 mg
hydrocodone	30 mg	Not applicable
hydromorphone	7.5 mg	1.5 mg
levorphanol	4 mg	2 mg
meperidine	300 mg	75 to 100 mg
morphine (around-the-clock dosing)	30 mg	10 mg
morphine (single or intermittent dosing)	60 mg	10 mg
oxycodone	30 mg	Not applicable

Nerve impulse travels through adrenergic nerve, causing it to release serotonin and norepinephrine. Amitriptyline blocks serotonin and norepinephrine reuptake by the nerves.

Back to Figure

Testosterone enters the cell and causes DHT to be released into the blood vessel. Dutasteride enters the cell and inhibits the production of DHT.

Back to Figure

In both illustrations, TNF receptors are attached to the bilayer cell membrane. In the first illustration, a macrophage releases TNF, which is attached to the receptor, causing inflammation. In the second illustration, etanercept is bound to the TNFs released by the macrophage, and the receptors are empty.

Back to Figure

Food is ingested through the mouth. Exenatide is absorbed into the bloodstream. Glucose output is decreased in the liver, glucose absorption is slowed in the small intestine, and insulin output is increased in the pancreas.

Back to Figure

In both illustrations, a layer of enterocytes is between intestinal lumen and the lymphatic system. Glycerol, cholesterol, and bile salts club together to form a micelle. In the first illustration, the enterocytes consist of chylomicron, consisting of glycerol, cholesterol, and bile salts in an envelope, cholesterol, and triglyceride. The chylomicron passes to the lymphatic system. In the second illustration, ezetimibe forms a layer between intestinal lumen and enterocytes. The enterocytes consist of bile salt and glycerol.

Back to Figure

In both illustrations, a parietal cell consists of a H<sub>2</sub> receptor. In the first illustration, histamine attaches itself to the receptor, resulting in the release of hydrogen and chloride ions. In the second illustration, famotidine is attached to the receptor, and prevents histamine from attaching itself to it.

Back to Figure

The bilayer smooth-muscle cell membrane consists of a muscarinic receptor. Ipratropium is attached to it in the cell exterior. It prevents acetylcholine released by cholinergic fiber from attaching itself to the receptor.

Back to Figure

The bilayer smooth-muscle cell membrane consists of a nitrate receptor. Isosorbide is attached to it in the cell exterior. The receptor activates nitric oxide in the cell interior, causing guanylate cyclase to release calcium ions from the cell and to produce cGMP.

Back to Figure

In the first illustration, 50S subunit with 23S rRNA and 30S subunit pass through the messenger RNA, forming a 70S initiation complex. The initiation complex, along with another complex consisting of amino acid and tRNA, form a polypeptide chain. In the second illustration, linezolid is attached to the 50S subunit, forming a nonfunctioning initiation complex.

Back to Figure

The bilayer cell membrane consists of a closed ion channel. Potassium ions are in the cell interior, and calcium, sodium, and magnesium ions are in the cell exterior. Memantine is attached to the channel, preventing glutamate to attach itself to it.

[Back to Figure](#)

In both illustrations, the bilayer myocardial cell membrane consists of a hormone receptor and an ion channel. In the first illustration, phosphodiesterase in the cell interior is along the membrane, between the receptor and the channel. It produces degraded cAMP and closes the channel. The closed channel blocks the calcium movement in the cell exterior. In the second illustration, milrinone is present in the cell interior, and phosphodiesterase is inhibited by it. cAMP is produced in the cell interior, and the channels are opened, causing calcium ions to move into the cell.

[Back to Figure](#)

The bilayer cell membrane of a beta cell consists of ATP-potassium channel and calcium channel. Nateglinide is attached to the ATP-potassium channel in the cell exterior, closing the channel. ATP is produced in the cell interior, and potassium ions remain inside the cell. The calcium ions enter the cell from the exterior. Insulin globules are attached to the cell membrane and are secreted to the cell exterior.

[Back to Figure](#)

The bilayer smooth muscle cell membrane consists of AT subscript 1. Olmesartan is attached to each AT subscript 1. In the cell exterior, angiotensin 1 forms angiotensin 2, which is prevented from being attached to AT subscript 1.

[Back to Figure](#)

In the first illustration, the proton pump in a parietal cell membrane releases potassium ion out of the stomach lumen and takes in hydrogen ion. Chloride ion also enters the lumen through a channel in the parietal cell membrane. In the second illustration, omeprazole blocks the proton pump, preventing the movement of potassium and hydrogen ions.

[Back to Figure](#)

The outer layer of the small intestine mucosa is irritated. Enterochromaffin cells over the irritated mucosa. Few 5-HT subscript 3 are attached to the 5-HT subscript 3 receptor sites of the vagus nerve, consisting of palonosetron. The movement of the nerve impulse up the nerve is blocked.

[Back to Figure](#)

In the first illustration, aldosterone is attached to the receptors of the distal convoluted tubule. The tubule consists of sodium ions and water that are reabsorbed by the blood. In the second illustration, spironolactone replaces aldosterone, preventing sodium and water reabsorption by the blood.

[Back to Figure](#)

Data from the table are as follows. Atropine is compatible with chlorpromazine, diphenhydramine, droperidol, glycopyrrolate, hydromorphone, hydroxyzine, meperidine, metoclopramide, midazolam, morphine, pentobarbital,

prochlorperazine, ranitidine, and scopolamine, incompatible with haloperidol, and the information on compatibility with dexamethasone, diazepam, furosemide, heparin, ketorolac, lidocaine, and lorazepam is not available. Chlorpromazine is compatible with diphenhydramine, droperidol, glycopyrrolate, hydromorphone, hydroxyzine, meperidine, metoclopramide, midazolam, prochlorperazine, ranitidine, and scopolamine, incompatible with heparin, morphine, and pentobarbital, and the information on compatibility with dexamethasone, diazepam, furosemide, haloperidol, ketorolac, lidocaine, and lorazepam is not available. Dexamethasone is compatible with hydromorphone, metoclopramide, and ranitidine, incompatible with diphenhydramine, and the information on compatibility with diazepam, diphenhydramine, droperidol, furosemide, haloperidol, heparin, hydroxyzine, ketorolac, lidocaine, lorazepam, meperidine, midazolam, morphine, pentobarbital, prochlorperazine, and scopolamine is not available. Diazepam is incompatible with glycopyrrolate, heparin, ketorolac, and ranitidine, and the information on compatibility with diphenhydramine, droperidol, furosemide, haloperidol, hydromorphone, hydroxyzine, lidocaine, lorazepam, meperidine, metoclopramide, midazolam, morphine, pentobarbital, prochlorperazine, and scopolamine. Diphenhydramine is compatible with droperidol, glycopyrrolate, hydromorphone, hydroxyzine, meperidine, metoclopramide, midazolam, morphine, prochlorperazine, ranitidine, scopolamine, incompatible with haloperidol and pentobarbital, and the information on compatibility with furosemide, heparin, ketorolac, lidocaine, and lorazepam is unavailable. Droperidol is compatible with glycopyrrolate, hydroxyzine, meperidine, metoclopramide, midazolam, morphine, prochlorperazine, and scopolamine, incompatible with furosemide, heparin, and pentobarbital, and the information on compatibility with haloperidol, hydromorphone, ketorolac, lidocaine, lorazepam, and ranitidine. Furosemide is compatible with heparin, incompatible with metoclopramide, and the information on compatibility with glycopyrrolate, haloperidol, hydromorphone, hydroxyzine, ketorolac, lidocaine, lorazepam, meperidine, midazolam, morphine, pentobarbital, prochlorperazine, ranitidine, and scopolamine is unavailable. Glycopyrrolate is compatible with haloperidol, hydromorphone, hydroxyzine, lidocaine, meperidine, midazolam, morphine, prochlorperazine, ranitidine, and scopolamine, incompatible with pentobarbital, and the information on compatibility with heparin, ketorolac, lorazepam, and metoclopramide is unavailable. Haloperidol is compatible with hydromorphone, incompatible with heparin, hydroxyzine, ketorolac, and morphine, and the information on compatibility with lidocaine, lorazepam, meperidine, metoclopramide, midazolam, pentobarbital, prochlorperazine, ranitidine, and scopolamine is not available. Heparin is compatible with lidocaine, metoclopramide, and morphine, incompatible with meperidine, and the information on compatibility with hydromorphone, hydroxyzine, ketorolac, lorazepam, midazolam, pentobarbital, prochlorperazine, ranitidine, and scopolamine is not available. Hydromorphone is compatible with hydroxyzine, lorazepam, midazolam, pentobarbital, ranitidine, and scopolamine, incompatible with ketorolac and prochlorperazine, and the information on compatibility with lidocaine, meperidine, metoclopramide, and morphine is not available. Hydroxyzine is compatible with lidocaine, meperidine,

metoclopramide, midazolam, morphine, prochlorperazine, ranitidine, and scopolamine, incompatible with ketorolac and pentobarbital, and the information on compatibility is not available for lorazepam. Ketorolac is incompatible with prochlorperazine, and the information on compatibility with lidocaine, lorazepam, meperidine, metoclopramide, midazolam, morphine, pentobarbital, ranitidine, and scopolamine is not available. Lidocaine is compatible with metoclopramide, and the information on compatibility with lorazepam, meperidine, midazolam, morphine, pentobarbital, prochlorperazine, ranitidine, and scopolamine is not available. Lorazepam is incompatible with ranitidine, and the information on compatibility with meperidine, midazolam, morphine, pentobarbital, prochlorperazine, and scopolamine is not available. Meperidine is compatible with metoclopramide, pentobarbital, prochlorperazine, ranitidine, scopolamine, and incompatible with midazolam and morphine. Metoclopramide is compatible with midazolam, morphine, prochlorperazine, ranitidine, and scopolamine, and the compatibility information with pentobarbital is not available. Midazolam is compatible with morphine and scopolamine, and incompatible with pentobarbital, prochlorperazine, and ranitidine. Morphine is compatible with prochlorperazine, ranitidine, and scopolamine, and incompatible with pentobarbital. Pentobarbital is compatible with scopolamine, and incompatible with prochlorperazine and ranitidine. Prochlorperazine is compatible with ranitidine and scopolamine. Ranitidine is compatible with scopolamine.
